INTRODUCTION

Welcome to the Celestron world of amateur astronomy! For more than a quarter of a century, Celestron has provided amateur astronomers with the tools needed to explore the universe. The Celestron CM-1100 and CM-1400 continues in this proud tradition combining large aperture optics with ease of use and portability. With a mirror diameter of 11 inches, your Celestron CM-1100 has a light gathering power of 1,593 times that of the unaided human eye, and the CM-1400 has a light gathering power of 2,581 times that of the unaided human eye. Yet despite their large apertures, the Celestron CM-1100 and CM-1400 optical systems are extremely compact and portable because they utilize the Schmidt-Cassegrain design. This means you can take your Celestron CM-1100 or CM-1400 to the mountains or desert or wherever you observe.

The Celestron CM-1100 and CM-1400 are made of the highest quality materials to ensure stability and durability. All this adds up to telescopes that will give you a lifetime of pleasure with a minimal amount of maintenance. And, your Celestron CM-1100 and CM-1400 are versatile — they grow as your interest in astronomy grows.

Your Celestron CM-1100 and CM-1400, are not limited to astronomical viewing alone. They can also be used for terrestrial viewing to study the world around you. All you need to do is take the time to familiarize yourself with your Celestron telescope and its operation.

NOTE

The CM-1100 and CM-1400 share the same mount and are basically the same with the exception of the larger aperture of the 14". So, this manual will basically discuss the CM-1100 but will discuss the CM-1400 when there are differences. Users of the CI-700 mount by itself will find complete assembly and operation instructions in the "AssemblingYour CM-1100" and "Using the Drive" sections of this manual.

Download from Www.Somanuals.com. All Manuals Search And Download.

How to Use This Manual

This manual is designed to instruct you in the proper use of your Celestron CM-1100 telescope. The instructions are for assembly, initial use, long term operation, and maintenance. There are seven major sections to the manual. The first section covers the proper procedure for setting up your Celestron CM-1100 telescope. This includes setting up the tripod, attaching the telescope to the mount, balancing the telescope, etc.

The second section deals with the basics of telescope use. Topics include focusing, aligning the finder, and taking your first look. The third section deals with the basics of astronomy which includes the celestial coordinate system, the motion of the stars, and polar alignment. The fourth section deals with celestial observing covering visual observations of the planets and deep-sky objects. Using both the setting circles and star hopping are discussed. The fifth section covers celestial photography working from the easiest to the most difficult. The last major section is on telescope maintenance, specifically on cleaning and collimation. **Keeping your CM-1100 in proper collimation is the single most important thing you can do to ensure it performs well.**

In addition to the major sections mentioned previously, there is a list of optional accessories for your Celestron CM-1100 that include a brief description of its purpose. This is the section to consult when you've mastered the basics and are ready for new, more challenging observations. The final part of this manual contains a list of objects that can be observed through your Celestron CM-1100 telescope. Included are the coordinates for each object, its brightness, and a code which indicates what type of an object it is. In addition, there is a list of bright stars used for aligning the setting circles.

Read the assembly instructions through completely before you attempt to set up your Celestron CM-1100 telescope. Then, once you've set up your Celestron CM-1100, read the section on "Telescope Basics" before you take it outside and use it. This will ensure that you are familiar with your telescope before you try to use it under a dark sky. Since it will take a few observing sessions to familiarize yourself with your Celestron CM-1100, you should keep this manual handy until you have fully mastered your telescope's operation. After that, save the manual for future reference.

A Word of Caution

Your Celestron CM-1100 is designed to give you hours of fun and rewarding observations. There are, however, a few things to consider before using your telescope that will ensure your safety and protect your equipment.

WARNING!

NEVER LOOK DIRECTLY AT THE SUN WITH THE NAKED EYE OR WITH A TELESCOPE. PERMANENT AND IRREVERSIBLE EYE DAMAGE MAY RESULT.

NEVER USE YOUR TELESCOPE TO PROJECT AN IMAGE OF THE SUN ONTO ANY SURFACE. INTERNAL HEAT BUILD-UP CAN DAMAGE THE TELESCOPE AND/OR ANY ACCESSORIES ATTACHED TO IT.

NEVER USE AN EYEPIECE SOLAR FILTER OR A HERSCHEL WEDGE. INTERNAL HEAT BUILD-UP INSIDE THE TELESCOPE CAN CAUSE THESE DEVICES TO CRACK OR BREAK, ALLOWING UNFILTERED SUNLIGHT TO PASS THROUGH TO THE EYE.

NEVER LEAVE THE TELESCOPE UNSUPERVISED, EITHER WHEN CHIL-

Download from Www.Somanuals.com. All Manuals Search And Download.

DREN ARE PRESENT OR ADULTS WHO MAY NOT BE FAMILIAR WITH THE CORRECT OPERATING PROCEDURES OF YOUR TELESCOPE.

NEVER POINT YOUR TELESCOPE AT THE SUN UNLESS YOU HAVE THE PROPER SOLAR FILTER. WHEN USING YOUR TELESCOPE WITH THE CORRECT SOLAR FILTER, ALWAYS COVER THE FINDER. ALTHOUGH SMALL IN APERTURE, THIS INSTRUMENT HAS ENOUGH LIGHT GATHERING POWER TO CAUSE PERMANENT AND IRREVERSIBLE EYE DAMAGE. IN ADDITION, THE IMAGE PROJECTED BY THE FINDER IS HOT ENOUGH TO BURN SKIN OR CLOTHING.

The Schmidt-Cassegrain Optical System

A telescope is nothing more than an instrument that collects and focuses light. The nature of the optical design determines how the light is focused. Some telescopes, known as refractors, use lenses while others, known as reflectors, use mirrors. The Schmidt-Cassegrain optical (or Schmidt-Cass for short) system uses a combination of mirrors and lenses and is referred to as a compound or catadioptric telescope. This unique design offers large diameter optics while maintaining very short tube lengths, making them extremely portable. This makes them extremely popular among amateur astronomers. The Schmidt-Cassegrain system consists of a zero power corrector plate, a spherical primary mirror, and a secondary mirror. Once light rays enter the optical system, they travel the length of the optical tube three times.

Inside the optical tube you will notice a black tube (not illustrated) that extends out from the center hole in the primary mirror. This is the primary baffle tube which prevents stray light from passing through to the eyepiece or camera without striking the primary or secondary mirrors.

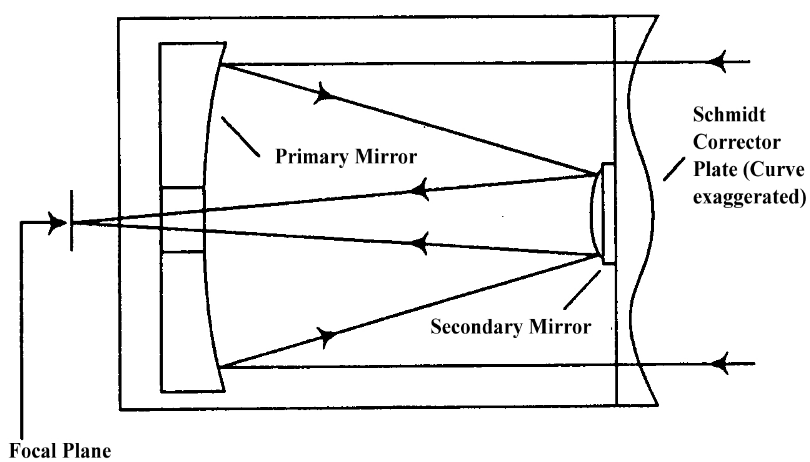

Figure 1-1

This cross-sectional diagram shows the light path of the Schmidt-Cassegrain optical system. Note that the light rays travel the length of the telescope tube three times, making this a compact optical design. Note that the curve of the corrector plate is greatly exaggerated.

Download from Www.Somanuals.com. All Manuals Search And Download.

ASSEMBLING YOUR CM-1100

This section covers the assembly instructions for your Celestron CM-1100 telescope. The Celestron CM-1100 should be set up indoors the first time so that it is easy to identify the various parts and familiarize yourself with the correct assembly procedure before attempting it outdoors.

The Celestron CM-1100 is a standard 11" Schmidt-Cassegrain telescope on a heavy-duty German equatorial mount. The Celestron CM-1100 comes standard with Starbright ™ enhanced multilayer aluminum coatings on the primary and secondary mirrors for increased reflectivity. Also, the corrector plate is fully coated to allow maximum light transmission. The Celestron CM-1100 is shipped in six boxes. One contains the telescope and is accompanied by a box that contains most of the standard accessories, which are:

- 26mm Plössl Ocular 1-1/4"
- Visual Back 1-1/4" (2" Visual Back on the CM-1400)
- Star Diagonal 1-1/4" (2" Mirror Diagonal for the CM-1400)
- 9x50mm Finderscope with Bracket
- Car Battery Adapter
- Lens Cap

In separate boxes are the following:

- Optical Tube Assembly
- Equatorial Mount and Counterweight Bar
- Tripod
- Central Column, Electronics Module, Polar Axis Finder and Hand Control
- One 23 Pound Counterweight (The CM-1400 come with two 25 lb. counterweights)
- Accessories for Optical Tube

Included is all the hardware needed to assemble the telescope.

Use the diagram on the following page (see Figure 2-1) to familiarize yourself with the various parts of your Celestron CM-1100 telescope.

Unpacking Your Celestron CM-1100

Remove all the pieces from their respective boxes and place on a flat, clear work area. A large floor space is ideal. When setting up your Celestron CM-1100) you must start with the tripod and work up from there. These instructions are laid out in the order each task must be performed.

Setting Up the Tripod

The tripod legs attach to a central column which together form the tripod to which the equatorial mount attaches. The tripod comes with two leg support brackets; a collapsible one that is already attached to the lower legs and a removable one that must be attached.   To set up the tripod:

1. Stand the tripod vertically on a level surface, with the feet facing down (See Figure 2-2).

2. Grab the lower portion of two of the tripod legs and lift them slightly off the ground so that the tripod is resting on the third leg.

3. Extend the tripod legs by pulling the tripod legs apart until the collapsible leg bracket is fully extended. (See Figure 2-3)

Before the tripod is ready to support the equatorial head and optical tube the center leg support brace must first be installed.

Figure 2-2

Figure 2-3

Download from Www.Somanuals.com. All Manuals Search And Download.

Attaching the Center Leg Brace

For maximum rigidity, the CI 700 tripod has a center leg brace that installs on to the threaded rod below the tripod head. This brace fits snugly against the tripod legs, increasing stability while reducing vibration and flexure. To attach the center leg brace:

1. Unscrew the tension knob from the threaded rod beneath the tripod head.

2. Place the center leg brace onto the threaded rod so that the cup on the end of each bracket contours to the curve of the tripod legs.

3. Rotate the tension knob back on the threaded rod until the brace is very snug against each tripod leg.

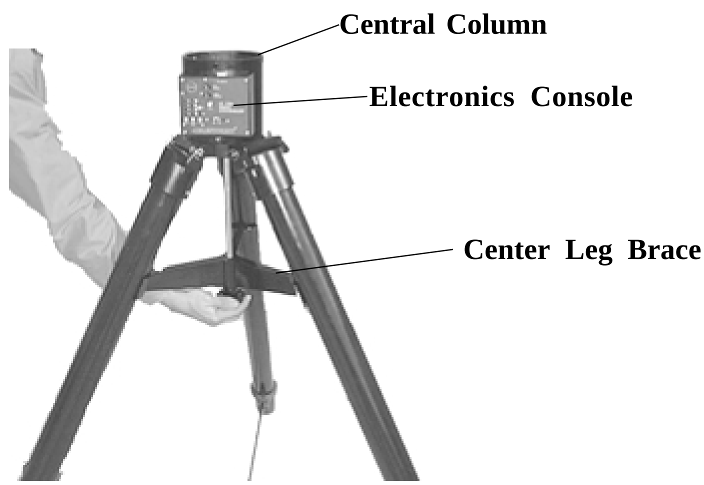

Figure 2-4

Attaching the Central Column

Before the equatorial mount head can be installed, the central column with the electronics module must be attached to the tripod. To attach the central column:

1. Position the central column so that the electronics module is right side up (see Figure 2-4).

2. Place the lower end of the central column over the tripod head.

3. Rotate the column until the three holes line up with the threaded holes on the side of the tripod head. The electronics console should be positioned directly between two of the tripod leg hinges to provide easy access to it even when the counterweight bar and counterweight(s) are attached.

4. Insert the three 3/8-16 button head cap screws provided through the holes in the central column and into the tripod head.

5. Tighten the screws to hold the column securely in place.

Download from Www.Somanuals.com. All Manuals Search And Download.

Attaching the Equatorial Mount

After the tripod is set up, you are ready to attach the equatorial mount. The equatorial mount is the platform to which the telescope attaches and allows you to move the telescope in right acsension and declination. The mount is also adjustable so you can orient the axis of rotation so that it is parallel with the Earth's axis of rotation (see the section on "Polar Alignment"). To attach the equatorial mount to the tripod:

1. Insert the base of the equatorial mount into the top of the central column.

2. Rotate the equatorial mount on the central column until the holes in the mount line up with those in the central column and the dec opening (where the counterweight shaft will go) is positioned directly over one of the tripod legs.

3. Insert the three remaining 3/8-16 cap screws and washers provided through the holes in the central pier and into the equatorial mount (see Figure 2-5).

4. Tighten the screws to hold the equatorial mount in place.

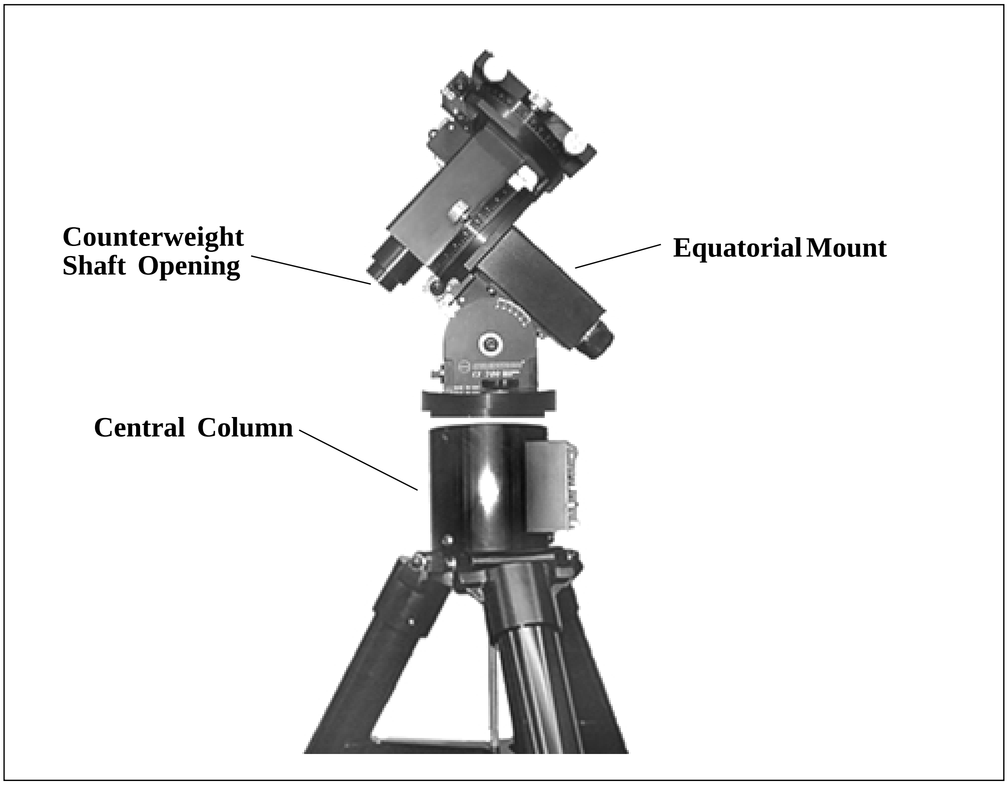

Figure 2-5

Download from Www.Somanuals.com. All Manuals Search And Download.

Installing the Counterweight Bar

To properly balance the telescope, the mount comes with a counterweight bar and one counterweight (the CM-1400 comes with two counterweights). The counterweight bar is located in the same box as the Equatorial Mount Head — in a cutout along the bottom of the shipping box. To install the counterweight bar:

1. Locate the opening in the equatorial mount on the DEC axis (see figure 2-6). It is opposite the telescope mounting platform.

2. Thread the counterweight bar into the opening until tight.

Once the bar is securely in place you are ready to attach the counterweight.

HINT

Since the fully assembled telescope is quite heavy, position the mount so that the tripod leg with the counterweight bar over it is pointing towards north before the tube assembly and counterweights are attached. This will make the polar alignment procedure much easier.

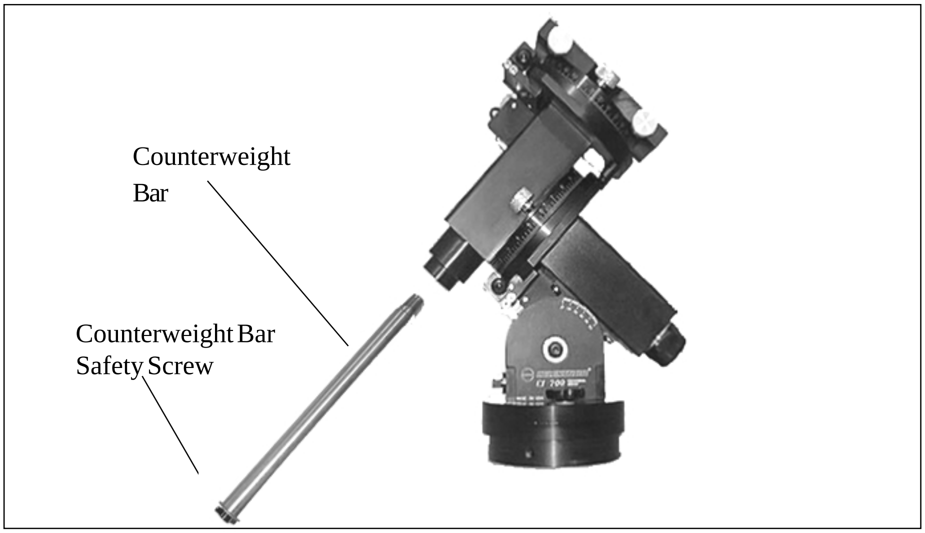

Figure 2-6

Installing the Counterweight

The Celestron CM-1100 comes standard with one 23 pound counterweight. The CM-1400 comes with two 25 pound counterweights. To install the counterweight(s):

1. Orient the mount so that the counterweight bar points toward the ground (see figure 2-7).

2. Remove the counterweight safety thumbscrew and washer on the end of the counterweight bar (i.e., opposite the end that attaches to the mount).

3. Loosen the set screw on the side of the counterweight.

4. Slide the counterweight onto the shaft.

5. Tighten the locking screw on the side of the weight to hold the counterweight in place.

6. Replace the counterweight safety thumbscrew and washer.

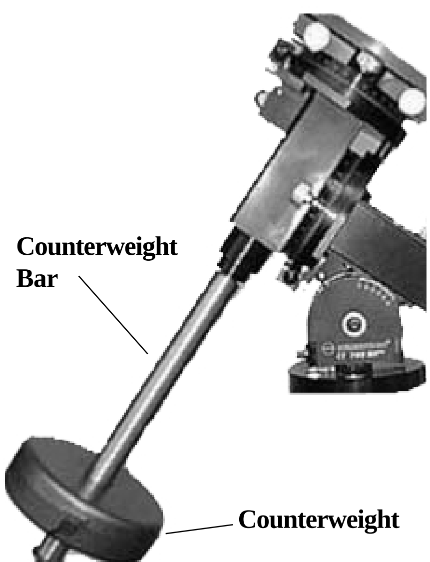

Figure 2-7

Download from Www.Somanuals.com. All Manuals Search And Download.

Attaching the Optical Tube to the Mount

The telescope attaches to the mount via a dovetail slide bar which is mounted along the bottom of the telescope. Before you attach the optical tube, make sure that the declination and right ascension clutch knobs are tight. This will ensure that the mount does not move suddenly while attaching the telescope. To mount the telescope tube:

1. Loosen the knobs on the side of the telescope mounting platform. This allows you to slide the dovetail bar on the telescope onto the mount.

2. Slide the dovetail bar on the telescope tube into the mounting platform of the mount. Slide the telescope so that the back of the dovetail bar is almost flush with the back of the mounting platform.

3. Tighten the locking knobs on the side of the mounting platform to hold the telescope in place.

4. Slide the dovetail slide bar safety clamp down the front end of the slide bar until it touches the mounting platform. This clamp is designed to keep the telescope from sliding off the mount in case the knobs on the side of the platform comes loose. It is best to wait until the telescope is balanced in R.A. and DEC before attaching the safety clamp (see "Balancing the Mount in DEC" later in this section).

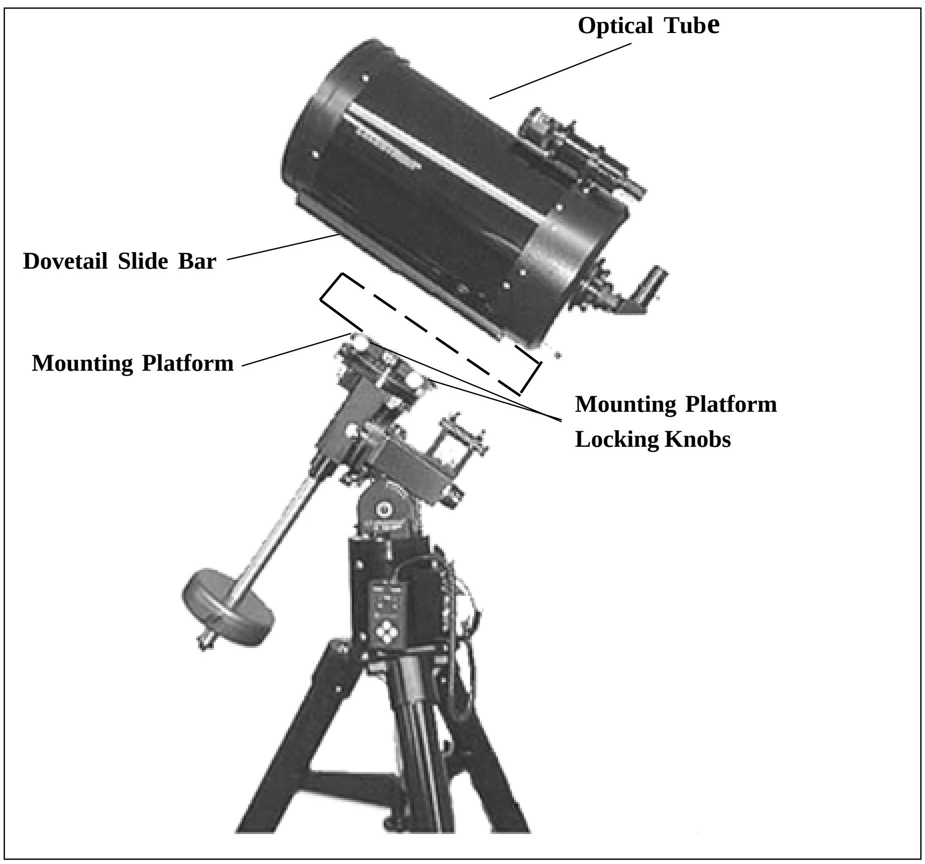

Figure 2-8

Download from Www.Somanuals.com. All Manuals Search And Download.

Attaching the Visual Back

The visual back is the accessory that allows you to attach all visual accessories to the telescope. To attach the visual back:

1. Remove the plastic cover on the rear cell.

2. Place the knurled slip ring on the visual back over the threads on the rear cell.

3. Hold the visual back with the set screw in a convenient position and rotate the knurled slip ring clockwise until tight.

Once this is done, you are ready to attach other accessories, such as eyepieces, diagonal prisms, etc.

If you want to remove the visual back, rotate the slip ring counterclockwise until it separates from the rear cell.

Installing the Star Diagonal

The star diagonal is a prism that diverts the light at a right angle to the light path of the telescope. This allows you to observe in positions that are physically more comfortable than if you looked straight through. To attach the star diagonal: **NOTE:** The CM-1400 uses a 2" mirror diagonal.

1. Turn the set screw on the visual back until its tip no longer extends into (i.e., obstructs) the inner diameter of the visual back.

2. Slide the chrome portion of the star diagonal into the visual back.

3. Tighten the set screw on the visual back to hold the star diagonal in place.

If you wish to change the orientation of the star diagonal, loosen the set screw on the visual back until the star diagonal rotates freely. Rotate the diagonal to the desired position and tighten the set screw.

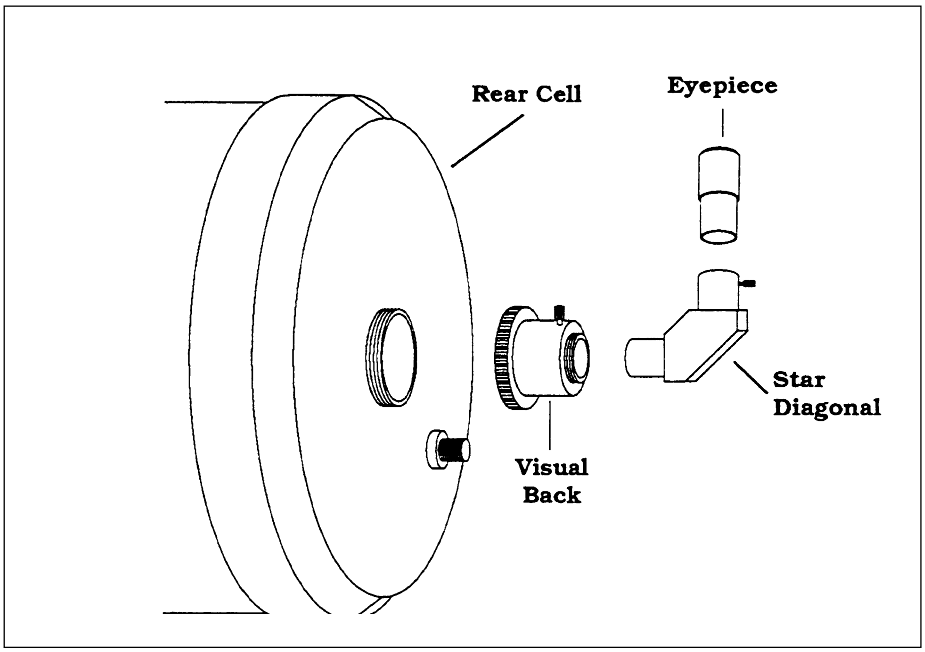

Figure 2-9

Download from Www.Somanuals.com. All Manuals Search And Download.

Installing the Eyepiece

The eyepiece, or ocular, is an optical element that magnifies the image focused by the telescope. The ocular(s) fit into either the visual back directly, the star diagonal, or the Erect Image Diagonal (purchased separately). To install an ocular:

1. Loosen the set screw on the star diagonal until the tip no longer extends into the inner diameter of the eyepiece end of the diagonal.

2. Slide the chrome portion of the eyepiece into the star diagonal.

3. Tighten the set screw on the star diagonal to hold the eyepiece in place.

To remove the eyepiece, loosen the set screw on the star diagonal and slide the eyepiece out. You can replace it with another ocular (purchased separately).

NOTE: The 2" mirror diagonal has a 1 1/4" eyepiece adapter to use 1 1/4" eyepieces. You may remove the adapter to use 2" eyepieces.

Eyepieces are commonly referred to by focal length and barrel diameter. The focal length of each eyepiece is printed on the eyepiece barrel. The longer the focal length (i.e., the larger the number) the lower the eyepiece power and the shorter the focal length (i.e., the smaller the number) the higher the magnification. Generally, you will use low-to-moderate power when viewing. For more information on how to determine power, see the section on "Calculating Magnification."

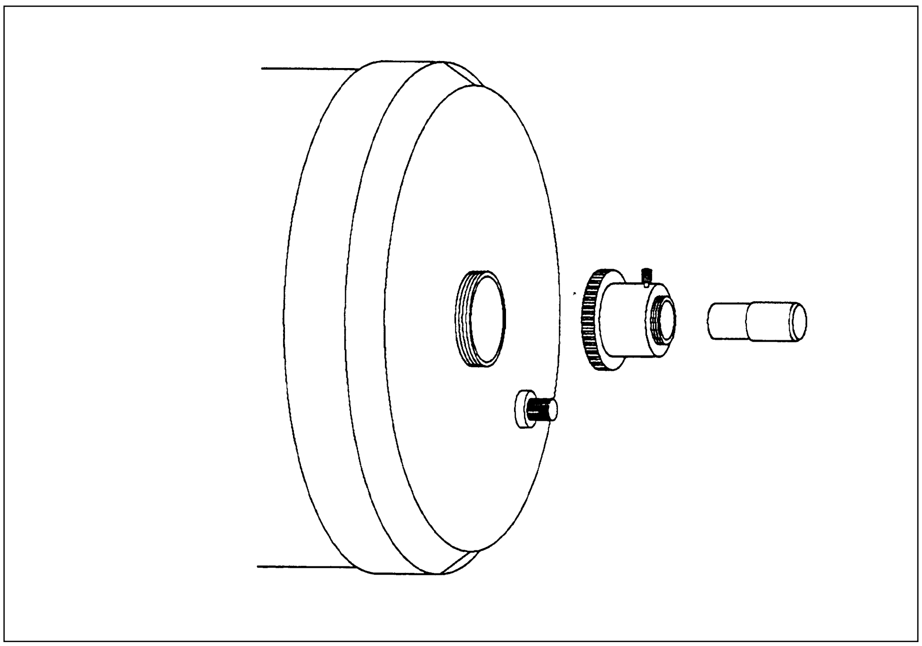

Figure 2-10

Download from Www.Somanuals.com. All Manuals Search And Download.

Installing the Finder

The CM-1100 telescope come with a 9x50 finderscope used to help you locate and center objects in the main field of your telescope. To accomplish this, the finder has a built-in cross-hair reticle that shows the optical center of the finderscope.

Start by removing the finder and hardware from the plastic wrapper. Included are the following:

- 9x50mm Finder
- Finder Bracket
- Rubber O-ring
- Three Nylon Tipped Thumbscrews (10-24x1/2")
- Two Allen Head Screws (8-32x1/2")

To install the finder:

1. Attach the bracket to the optical tube. To do this, place the curved portion of the bracket with the slot over the two holes in the rear cell. The bracket should be oriented so that the rings that hold the finder are over the telescope tube, not the rear cell (see Figure 2-1). Start threading the screws in by hand and tighten fully with an Allen wrench.

2. Partially thread-in the three nylon-tipped thumbscrews that hold the finder in place inside the bracket. Tighten the screws until the nylon heads are flush with the inner diameter of the bracket ring. Do **NOT** thread them in completely or they will interfere with the placement of the finder. (Having the screws in place when the finder is installed will be easier than trying to insert the screws after the finder has been installed.)

3. Slide the rubber O-ring over the back of the finder (it will **NOT** fit over the objective end of the finder). It may need to be stretched a little. Once on the main body of the finder, slide it up about one inch from the end of the finder.

4. Rotate the finder until one cross hair is parallel to the R.A. axis and the other is parallel to the DEC axis.

5. Slide the eyepiece end of the finder into the front of the bracket.

6. Slightly tighten the three nylon tipped thumbscrews on the front ring of the bracket to hold the finder in place.

7. Once on, push the finder back until the O-ring is snug inside the back ring of the finder bracket.

8. Hand tighten the three nylon tipped thumbscrews until snug.

Download from Www.Somanuals.com. All Manuals Search And Download.

Installing the Polar Finder

To aid in polar aligning the mount, your telescope comes standard with a Polar Housing Finder. It installs directly on top of the polar housing of the mount. To install the Polar Finder:

1. Locate the Polar Finder assembly. The Polar Finder assembly consists of the polar finder, mounting bracket and knurled mounting screw (see Figure 2.11).

2. Place the Polar Finder Assembly on top of the polar axis housing so that the mounting stop on the metal bracket sits flush against the rear of the polar housing.

3. Secure the Polar Finder Assembly to the mount by threading the Knurled Mounting Screw into the threaded hole on top of the Polar Housing.

The Polar Axis Finder is now installed and ready to use. To learn how to polar align the mount using the Polar Axis Finder, refer to the Astronomy Basics section of the manual.

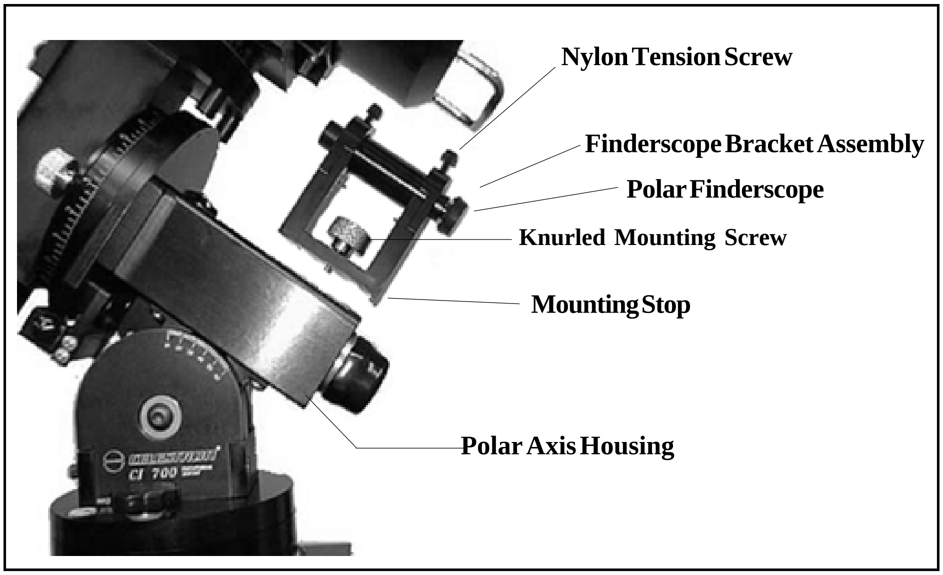

Figure 2-11

Download from Www.Somanuals.com. All Manuals Search And Download.

Moving the Telescope in R.A. and DEC

Once set up, you need to point your telescope at various portions of the sky to observe different objects. To make rough adjustments, loosen the R.A. and DEC clutch knobs slightly and move the telescope in the desired direction. Both the R.A. and DEC axis have two knobs to clutch down each axis of the telescope. To loosen the clutches on the telescope, rotate the clutch knobs (see figure below) counterclockwise. Once your have found your desired object in the finderscope, rotate the clutch knobs on each axis clockwise to lock the telescope in place.

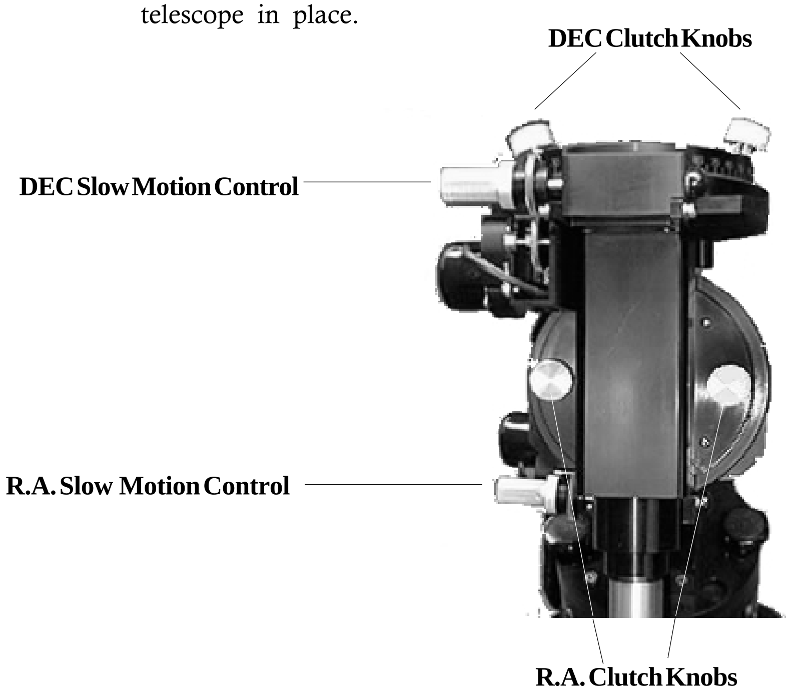

Figure 2-12

Using the Slow Motion Controls

The CI 700 mount is equipped with slow motion controls on both the R.A. and Declination axis. Each slow motion control has a clutch mechanism that allows you to override the tracking motor and adjust the amount of tension when turning the knob. To adjust the clutch mechanism, hold the slow motion knob with one hand, and rotate the clutch wheel with your other hand. Rotate the clutch wheel clockwise (downward) to increase the tension on the slow motion control and counterclockwise (upward) to decrease the tension.

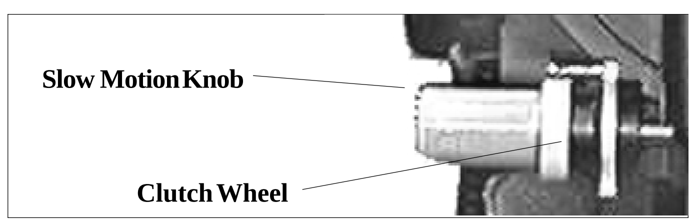

Figure 2-13

Download from Www.Somanuals.com. All Manuals Search And Download.

Adjusting the Mount

In order for the clock drive to track accurately, the telescope's axis of rotation must be parallel to the Earth's axis of rotation, a process known as polar alignment. Polar alignment is achieved **NOT** by moving the telescope in R.A. or DEC, but by adjusting the mount vertically, which is called altitude, and horizontally, which is called azimuth. This section simply covers the correct movement of the telescope during the polar alignment process. The actual process of polar alignment, that is making the telescope's axis of rotation parallel to the Earth's, is described later in this manual in the section on "Polar Alignment."

To adjust the mount in altitude:

1. Locate the altitude adjustment bolt just above the tripod column (see figure 2-14).

2. Using the 7/32" Allen wrench provided, turn the altitude adjustment bolt until the mount is at the right elevation.

The total altitude range is from 13° to 65°. With the 23 lb counterweight attached to the counterweight shaft, the equatorial head can go as low as 20° without hitting the tripod leg.

To adjust the mount in azimuth:

1. Locate the azimuth adjustment bolt on the flat portion of the tripod column.

2. Loosen the two azimuth lock knobs located on the top of the tripod column.

3. Turn the azimuth adjustment bolt with the 7/32" Allen wrench until the polar axis is pointing in the right direction.

4. Tighten the azimuth lock knobs to hold the mount in place.

The mount can be moved ± 7° in azimuth using these bolts.

Keep in mind that adjusting the mount is done during the polar alignment process only. Once polar aligned, the mount must **NOT** be moved. Pointing the telescope is done by moving the mount in right ascension and declination, as described earlier in this manual. Once the appropriate adjustments have been made and you are aligned on the celestial pole, turn the clock drive on and the telescope will track.

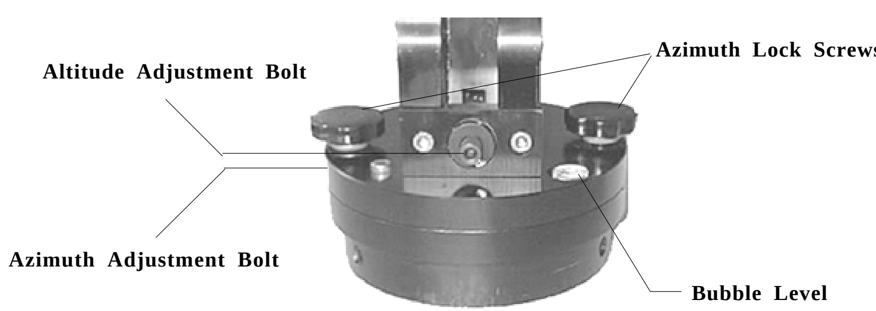

Figure 2-14

Download from Www.Somanuals.com. All Manuals Search And Download.

Balancing the Mount in R.A.

To eliminate undue stress on the mount, the telescope should be properly balanced around the polar axis. Proper balancing is crucial for accurate tracking. To balance the mount:

1. Verify that the telescope securing knobs on the telescope mounting platform are tight.

2. Loosen the R.A. clutch knobs and position the telescope off to one side of the mount. The counterweight bar will extend horizontally on the opposite side of the mount.

3. Release the telescope — **GRADUALLY** — to see which way the telescope "rolls."

4. Loosen the set screws on the side of the counterweight so it can be moved the length of the counterweight bar.

5. Move the counterweight to a point where it balances the telescope (i.e., the telescope remains stationary when the R.A. clutch knobs are loose).

6. Tighten the set screw on the counterweight to hold it in place.

While the above instructions describe a perfect balance arrangement, there should be a **SLIGHT** imbalance to ensure the best possible tracking. When the scope is on the west side of the mount the counterweight should be slightly imbalanced to the counterweight bar side. And when the tube is on the east side of the mount there should be a slight imbalance toward the telescope side. This is done so that the worm gear is pushing against a slight load. **The amount of the imbalance is very slight.** When taking astrophotographs, this balance process can be done for the specific area at which the telescope is pointing to further optimize tracking accuracy.

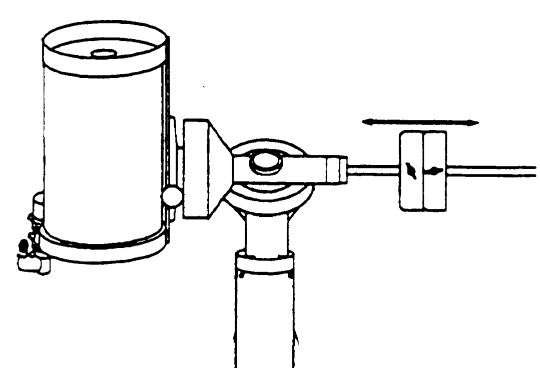

Figure 2-15

With the standard accessories attached, the counterweight should be at the far end of the counterweight bar.

Download from Www.Somanuals.com. All Manuals Search And Download.

Balancing the Mount in DEC

Although the telescope does not track in declination, the telescope should also be balanced in this axis to prevent any sudden motions when the DEC clutch knob is loose. To balance the telescope in DEC:

1. Loosen the R.A. clutch knobs and rotate the telescope so that it is on one side of the mount (i.e., as described in the previous section on "Balancing the Mount in R.A.").

2. Tighten the R.A. clutch knobs to hold the telescope in place.

3. Loosen the DEC clutch knobs and rotate the telescope until the tube is parallel to the ground.

4. Release the tube — **GRADUALLY** — to see which way it rotates around the declination axis. **DO NOT LET GO OF THE TELESCOPE TUBE COMPLETELY!**

5. **Slightly** loosen the knobs that holds the telescope to the mounting platform and slide the telescope either forward or backward until it remains stationary when the DEC clutch is loose. **Do NOT let go of the telescope tube while the knob on the mounting platform is loose.**

6. Tighten the knobs on the telescope mounting platform to hold the telescope in place.

Once the telescope is balanced in declination, slide the dovetail bar safety clamp down the front of the telescope's slide bar until it touches the mounting platform and tighten the locking bolt (see Figure 2-16). This not only acts as a safety in case the mounting platform knobs are loosened, but will also allow you to put the tube on the mount in the exact same position each time for perfect balance.

Like R.A. balance, these are general balance instructions and will reduce undue stress on the mount. When taking astrophotographs, this balance process should be done for the specific area at which the telescope is pointing.

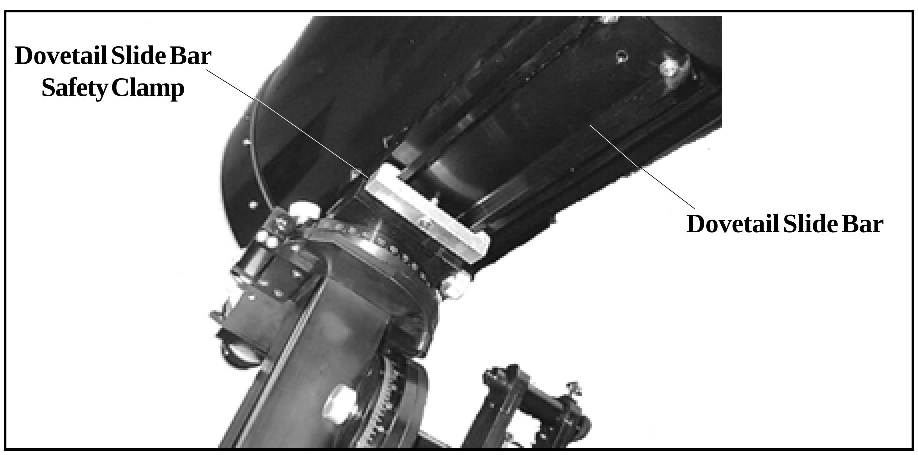

Figure 2-16

With the standard accessories attached, the end of the dovetail bar should be almost flush with the end of the telescope mounting platform.

Download from Www.Somanuals.com. All Manuals Search And Download.

Transporting Your Celestron CM-1100

Because of the Celestron CM-1100's size and weight, you should **ALWAYS** remove the telescope from the mount when moving the telescope. To do so:

1. Take the telescope off of the mount and return it to its shipping box.
2. Remove the counterweight from the counterweight bar.
3. Remove the counterweight bar from the mount.
4. Remove the finderscope from the optical tube.
5. Take the equatorial mount off of the central column.
6. Remove the center leg brace from the tripod.
7. Collapse the tripod legs inward, towards each other.

The telescope is now broken down into enough pieces to be easily transported.

Storing Your Celestron CM-1100

When not in use, your Celestron CM-1100 can be left fully assembled and set up. However, all lens and eyepiece covers should be put back in place. This will reduce the amount of dust build-up on all optical surfaces and reduce the number of times you need to clean the instrument. You may want to return everything to its original shipping container and store it there. If this is the case, all optical surfaces should still be covered to prevent dust accumulation.

If you are in the field, and plan on being there for a few days, use a plastic tarp to cover the telescope and mount.

Download from Www.Somanuals.com. All Manuals Search And Download.

Technical Specifications

Below is pertinent technical information on your Celestron CM-1100 telescope that you may find useful.

OPTICAL TUBE:	CM-1100	CM-1400
Optical System:	Schmidt-Cassegrain	Schmidt-Cassegrain
Aperture:	11" (279mm)	14" (356mm)
Focal Length:	2800mm (110.2")	3910mm (153.9")
F/ratio:	f/10	f/11
Highest Useful Power Magnification:	660x	840x
Lowest Useful Power Magnification:	42x	50x
Resolution (arc seconds):	0.41	0.33
Photographic Resolution:	200 lines/mm	182 lines/mm
Light Gathering Power:	1593x	2581x
Limiting Visual Magnitude:	14.7	15.3
Near Focus		
with eyepiece:	60'	175'
with camera:	60'	225'
Optical Tube Length:	25"	32"
Weight		
Optical Tube:	27.5 lbs.	45 lbs.

DEC AXIS:

- All machined stainless steel and aluminum
- 5.625 diameter precision bronze worm gear, 180 tooth. AGMA quality 10.
- .4375 diameter precision 303 stainless steel worm. AGMA quality 10. Dual bearing supported.
- One inch diameter solid shaft, centerless ground
- Two 2" preloaded Tapper Roller Bearings, pre-loading the shaft.
- Bearing preload is independent of clutch tension.
- Slip Clutch-Variable friction two knob adjustment
- 5.25" laser engraved setting circle, 1 degree increments.
- 182 oz/in Stepper Motor - .50 arc second steps
- Removable stainless steel counterweight shaft
- Dovetail saddle plate – allowing for interchanging of any tube assembly
- Instrument Weight of 60 Lbs

POLAR AXIS:

- All machined stainless steel and aluminum
- 5.625 diameter precision bronze worm gear, 180 tooth. AGMA quality 10.
- .4375 diameter precision 303 stainless steel worm. AGMA quality 10. Dual bearing supported.
- One inch diameter solid shaft, centerless ground
- Two 2" preloaded Tapper Roller Bearings, pre-loading the shaft.
- Bearing preload is independent of clutch tension.
- Slip Clutch-Variable friction two knob adjustment
- 5.25" driven laser engraved setting circle, 5 minute increments (Northern Hemisphere only)
- 182 oz/in Stepper Motor - .50 arc second steps
- Latitude adjustment 20 to 65 degrees with counterweights. Total travel is 13 to 65 degrees.
- Azimuth adjustment, bi-directional +/- 7 degrees

Download from Www.Somanuals.com. All Manuals Search And Download.

TRIPOD:

- All machined aluminum
- Semi-pier Tripod Design
- Fixed hieght Tripod with dual leg support
- Tripod legs are 48.5" long
- Tripod hieght is 49" high (fully extended with column attached)
- Tripod weight approximately 20 pounds
- Weight of equatorial head 31 pounds

CONTROL SYSTEM:

- Diamond push button pattern
- Hand Control: Reversible R.A. and DEC, Autoguider ready (use an autoguider and the hand control at the same time)
- Two photo guide rates: .3x, and .5x sidereal
- Three slew rates: 8x, 16x, and 20x (double button hand control, see chapter on Hand Control use)
- Quartz tracking rates; Sidereal, Solar, Lunar, King
- Periodic Error Correction (PEC)
- Accepts Auto-Guider Systems
- Northern and Southern Hemisphere operation
- Backlash compensation for declination axis.
- 12 Volt DC - 500 MA power use

Note: All specifications are stated for the Celestron CM telescopes using the standard accessories. Also, these specifications are approximate and subject to change without notice.

Once your telescope is fully assembled, you are ready for your first look. This section deals with some of the basics of telescope operation.

Image Orientation

The image orientation changes depending on how the eyepiece is inserted into the telescope. When using the star diagonal, the image is right-side-up, but reversed from left-to-right (i.e., reverted). If inserting the eyepiece directly into the visual back (i.e., without the star diagonal), the image is upside-down and reversed from left-to-right (i.e., inverted). This is normal for the Schmidt-Cassegrain design and applies to the telescope's finder as well.

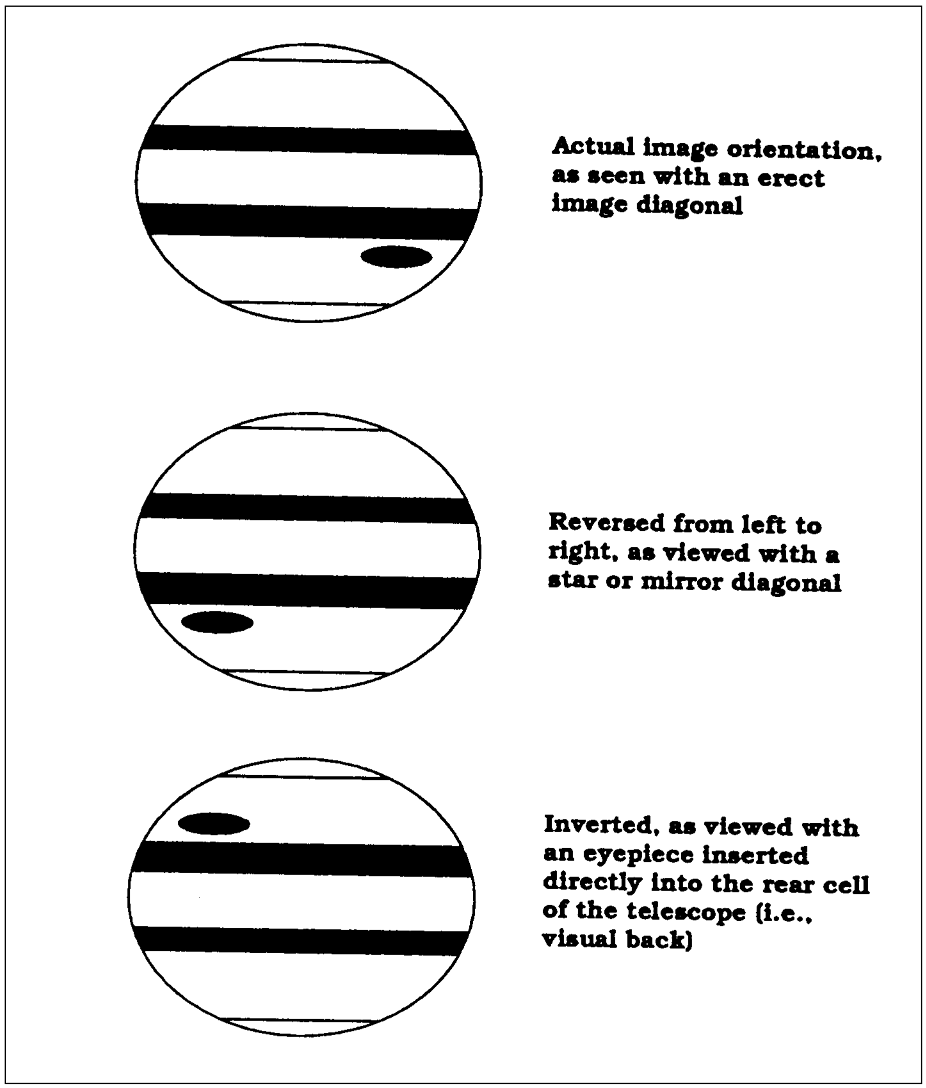

Figure 3-1

These simplified drawings of the planet Jupiter illustrate the different image orientations obtained when using various viewing configurations.

Download from Www.Somanuals.com. All Manuals Search And Download.

Focusing

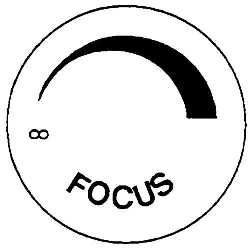

Figure 3-2

The decal on the end of the focus knob shows the correct rotational direction for focusing the CM-1100.

The Celestron CM-1100 focusing mechanism controls the primary mirror which is mounted on a ring which slides back and forth on the primary baffle tube. The focusing knob, which moves the primary mirror, is on the rear cell of the telescope just right of the star diagonal and eyepiece. Turn the focusing knob until the image is sharp. If the knob will not turn, it has reached the end of its travel on the focusing mechanism. Turn the knob in the opposite direction until the image is sharp. Once an image is in focus, turn the knob clockwise to focus on a closer object and counterclockwise for a more distant object. A single turn of the focusing knob moves the primary mirror only slightly. Therefore, it will take many turns (about 40) to go from close focus (approximately 65 feet) to infinity.

For critical focusing, both visually and photographically, turn the focus knob counterclockwise until the image is sharp. Turning the focusing knob in this direction pushes the primary mirror forward, or against the pull of gravity, which minimizes any mirror shift.

When working with any optical instrument, there are a few things to remember to ensure you get the best possible image.

- Never look through window glass. Glass found in household windows is optically imperfect, and as a result, may vary in thickness from one part of a window to the next. This inconsistency can and will affect the ability to focus your telescope. In most cases you will not be able to achieve a truly sharp image. In some cases, you may actually see a double image.

- Never look across or over objects that are producing heat waves. This includes asphalt parking lots on hot summer days or building rooftops.

- Hazy skies, fog, and mist can also make it difficult to focus when viewing terrestrially. The amount of detail seen under these conditions is greatly reduced. Also, when photographing under these conditions, the processed film may come out a little grainier than normal with lower contrast.

- When using your telescope as a telephoto lens, the split screen or microprism focuser of the 35mm SLR camera may “black out.” This is common with all long focal length lenses. If this happens, use the ground glass portion of your focusing screen. To achieve a very sharp focus you may consider using a focusing magnifier. (These are readily available from your local camera store.)

- If you wear corrective lenses (specifically glasses), you may want to remove them when observing with an eyepiece attached to the telescope. When using a camera, however, you should always wear corrective lenses to ensure the sharpest possible focus. If you have astigmatism, corrective lenses must be worn at all times.

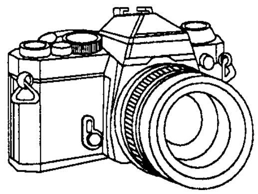
General Photography Hints



Your Celestron CM-1100 can be used for both terrestrial and astronomical photography. Your Celestron CM-1100 has a fixed aperture and, as a result, a fixed f/ratio. To properly expose your subjects photographically you need to set your shutter speed accordingly. Most 35mm single lens reflex (SLR) cameras offer through-the-lens metering which lets you know if your picture is under or overexposed. This is more of a consideration when doing terrestrial photography, where exposure times are measured in fractions of a second. In astrophotography, the exposures are much longer, requiring that you use the "B" setting on your camera. The actual exposure time is determined by how long you keep the shutter open.

To reduce vibration when tripping the shutter, use a cable release. Releasing the shutter manually can cause vibration, something that produces blurred photos. A cable release will keep your hands clear of the camera and telescope, thus reducing the possibility of shaking the telescope. Mechanical shutter releases can be used, though air type releases are best.

Aligning the Finder

The Celestron CM-1100 comes with an 9x50mm finder which helps in aiming the main telescope at distant objects that are hard to find in the narrow field of the telescope. The first number used to describe the finder is the power while the second number is the diameter of the objective lens in millimeters. This means the 9x50 finder is 9 power and has a 50mm objective lens. Incidentally, power is always compared to the unaided human eye. So a 9 power finder magnifies images nine times more than the human eye.

To make the alignment process a little easier, you should perform this task in the daytime when it is easier to locate objects in the telescope without the finder. To align the finder:

1. Choose a conspicuous object that is in excess of one mile away. This will eliminate any possible parallax effect.
2. Point your telescope at the object you selected and center it in the main optics of the telescope.
3. Check the finder to see where it is located in the field of view.
4. Adjust the screws on the finder bracket, tightening one while loosening another, until the cross hairs are centered on the target.
5. Tighten each set screw a quarter of a turn to ensure that they will not come loose easily.

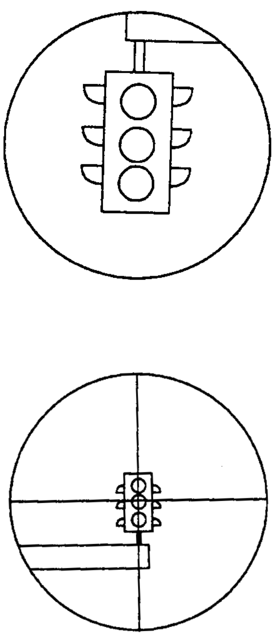


Figure 3-3

TOP: The image as seen through the telescope. BOTTOM: The image as seen through the finder.

Your First Look

With the telescope fully assembled and all the accessories attached, you are ready for your first look. Your first look should be done in the daytime when it is easier to locate the locking clutches. This will help to familiarize you with your telescope, thus making it easier to use at night.

Daytime Observing

As mentioned in the introduction, your Celestron CM-1100 telescope works well as a terrestrial spotting scope. When not used to examine objects in the night sky, it can be used to study objects here on Earth.

WARNING !

NEVER POINT YOUR TELESCOPE AT THE SUN UNLESS YOU HAVE THE PROPER SOLAR FILTER. PERMANENT AND IRREVERSIBLE EYE DAMAGE MAY RESULT AS WELL AS DAMAGE TO YOUR TELESCOPE. ALSO, NEVER LEAVE YOUR TELESCOPE UNATTENDED DURING A DAYTIME OBSERVING SESSION, ESPECIALLY WHEN CHILDREN ARE PRESENT.

1. Find a distant object that is fairly bright.
2. Insert a low power eyepiece (one with a large focal length) into the telescope.
3. Adjust the R.A. and DEC clutch knobs if needed and point the telescope in the direction of the object you selected.
4. Locate the object in your finder.
5. Move the telescope — by hand — until the object is centered in the finder.
6. Look through the main optics and the object will be there (if you aligned the finder first).

Try using different optional eyepieces to see how the field changes with various magnifications.

Download from Www.Somanuals.com. All Manuals Search And Download.

Nighttime Observing

Looking at objects in the sky is quite different than looking at objects on Earth. For one, many objects seen in the daytime are easy to see with the naked eye and can be located in the telescope by using landmarks. In the night sky many objects are not visible to the naked eye. To make things easier, you are better off starting with a bright object like the Moon or one of the planets.

1. Orient the telescope so that the polar axis is pointing as close to true north as possible. You can use a landmark that you know faces north to get you in the general direction.

2. Adjust the tripod legs until the mount is level.

3. Adjust the mount until the latitude indicator points to the latitude of the site from which you are observing.

4. Insert a low power eyepiece (i.e., one with a large focal length) into the telescope to give you the widest field possible.

5. Turn the clock drive on.

6. Loosen the right ascension and declination clutch knobs and point the telescope at the desired target. The Moon or one of the brighter planets is an ideal first target.

7. Locate the object in the finder, center it, and then look through the telescope.

8. Turn the focus knob until the image is sharp.

9. Take your time and study your subject. If observing the Moon, look for small details in the craters.

That's all there is to using your Celestron CM-1100. However, don't limit your view of an object to a single eyepiece. After a few minutes, try using a different optional eyepiece, a more powerful one. This gives you an idea of how the field of view changes. Center your target and focus. Once again, if observing the Moon you will be looking at a few craters at the same time.

NOTE: If not using the clock drive, the stars will appear to drift out of the field of view. This is due to the Earth's rotation. In fact, anything in the sky, day or night, will drift out unless the telescope has been polar aligned and the clock drive is running. There is more on this in the section on "Polar Alignment."

Calculating Magnification

You can change the power of your Celestron CM-1100 telescope just by changing the eyepiece (ocular). To determine the magnification of your Celestron CM-1100, simply divide the focal length of the telescope by the focal length of the eyepiece used. In equation format, the formula looks like this:

$$\text{Magnification} = \frac{\text{Focal Length of Telescope (mm)}}{\text{Focal Length of Eyepiece (mm)}}$$

Let’s say, for example, that you are using the standard 26mm eyepiece. To determine the magnification you simply divide the focal length of your Celestron CM-1100 (2800mm) by the focal length of the eyepiece (26mm). Dividing 2800 by 26 yields a magnification of 108 power.

Although the power is variable, each instrument — under average skies — has a limit to the highest useful magnification. The general rule is that 60 power can be used for every inch of aperture. For example, the Celestron CM-1100 is 11" in diameter. Multiplying 11 by 60 gives a maximum useful magnification of 660 power. Although this is the maximum useful magnification, most observing is done in the range of 20 to 35 power for every inch of aperture which is 220 to 385 times for the CM-1100.

Determining Field of View

Determining the field of view is important if you want to get an idea of the angular size of the object you are observing. To calculate the actual field of view, divide the apparent field of the eyepiece (supplied by the eyepiece manufacturer) by the magnification. In equation format, the formula looks like this:

$$\text{True Field} = \frac{\text{Apparent Field of Eyepiece}}{\text{Magnification}}$$

As you can see, before determining the field of view, you must figure the magnification. Using the example in the previous section, we can determine the field of view using the same 26mm eyepiece. The 26mm Plössl eyepiece has an apparent field of view of 50°. Divide the 50° by the magnification, which is 108 power. This yields an actual field of .46°, or about one half of a degree.

To convert degrees to feet at 1,000 yards, which is more useful for terrestrial observing, simply multiply by 52.5. Continuing with our example, multiply the angular field .46° by 52.5. This produces a linear field width of 24.2 feet at a distance of one thousand yards.

The apparent field of each eyepiece that Celestron manufactures is found in the Celestron Accessory Catalog (#93685).

ASTRONOMY BASICS

The following section deals with observational astronomy in general. It includes information on the night sky, polar alignment, and using your telescope for astronomical observing.

The Celestial Coordinate System

In order to help find objects in the sky, astronomers use a celestial coordinate system which is similar to our geographical coordinate system here on Earth. The celestial coordinate system has poles, lines of longitude and latitude, and an equator. For the most part, these remain fixed against the background stars.

The celestial equator runs 360 degrees around the Earth and separates the northern celestial hemisphere from the southern. Like the Earth's equator, it bears a reading of zero degrees. On Earth this would be latitude. However, in the sky this is referred to as declination, or DEC for short. Lines of declination are named for their angular distance above and below the celestial equator. The lines are broken down into degrees, minutes and seconds of arc. Declinations south of the equator carry a minus sign (-) in front of the coordinate and those north of the celestial equator are either blank (i.e., no designation) or preceded by a plus sign (+).

The celestial equivalent of longitude is called Right Ascension, or R.A. for short. Like the Earth's lines of longitude, they run from pole to pole and are evenly spaced 15 degrees apart. Although the longitude lines are separated by an angular distance, they are also a measure of time. Each line of longitude is one hour apart from the next. Since the Earth rotates once every 24 hours, there are 24 lines total. As a result, the R.A. coordinates are marked off in units of time. It begins with an arbitrary point in the constellation of Pisces designated as 0 hours, 0 minutes, 0 seconds. All other points are designated by how far (i.e., how long) they lag behind this coordinate after it passes overhead moving towards the west.

Your Celestron CM-1100 telescope comes equipped with setting circles that translate the celestial coordinates into a precise location for the telescope to point. The setting circles will not work properly until you have polar aligned the telescope and aligned the R.A. setting circle.

Motion of the Stars

The daily motion of the Sun across the sky is familiar to even the most casual observer. This daily trek is not the Sun moving as early astronomers thought, but the result of the Earth's rotation. The Earth's rotation also causes the stars to do the same, scribing out a large circle as the Earth completes one rotation. The size of that circular path a star follows depends on where it is in the sky. Stars near the celestial equator form the largest circles rising in the east and setting in the west. Moving toward the north celestial pole, the point around which the stars in the northern hemisphere appear to rotate, these circles become smaller. Stars in the mid-celestial latitudes rise in the north-east and set in the northwest. Stars at high celestial latitudes are always above the horizon, and are said to be circumpolar because they never rise and never set. You will never see the stars complete one circle because the sunlight during the day washes out the starlight. However, part of this circular motion of stars in this region of the sky can be seen by setting up a camera on a tripod and opening the shutter for a couple hours. The processed film will reveal semicircles that revolve around the pole. (This description of stellar motion also applies to the southern hemisphere except all stars south of the celestial equator move around the south celestial pole.)

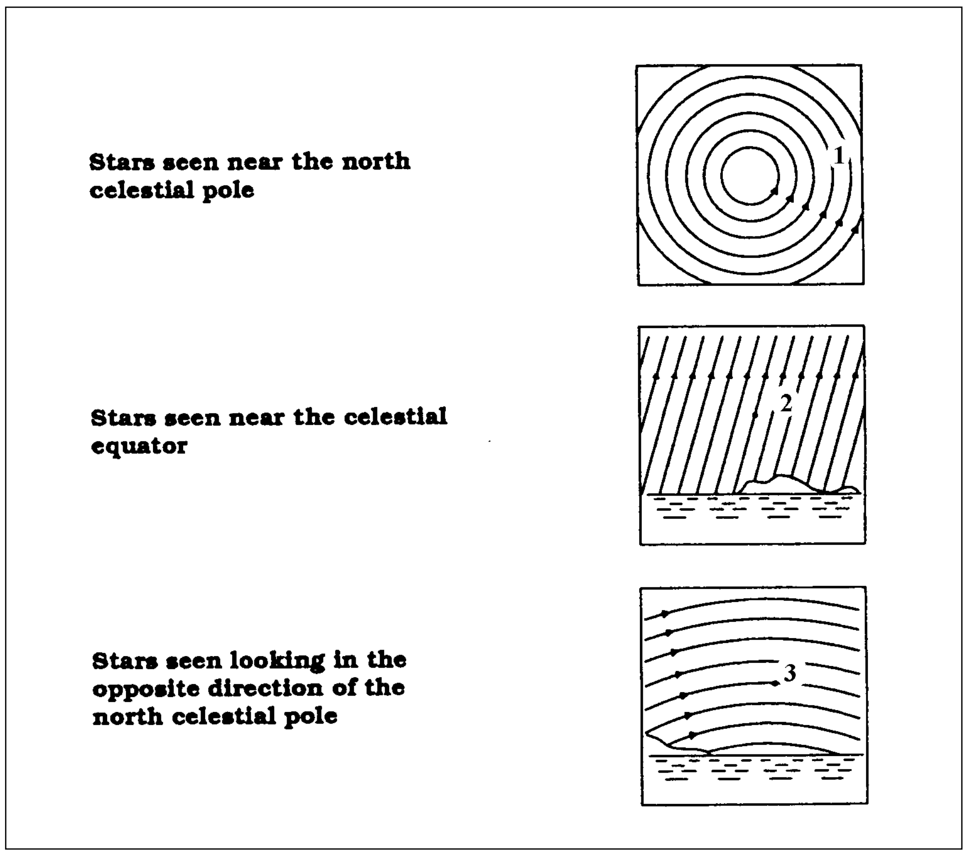

Figure 4-2

All stars appear to rotate around the celestial poles. However, the appearance of this motion varies depending on where you are looking in the sky. Near the north celestial pole the stars scribe out recognizable circles centered on the pole (1). Stars near the celestial equator also follow circular paths around the pole. But, the complete path is interrupted by the horizon. These appear to rise in the east and set in the west (2). Looking toward the opposite pole, stars curve or arc in the opposite direction scribing a circle around the opposite pole (3).

Download from Www.Somanuals.com. All Manuals Search And Download.

Polar Alignment

In order for the telescope to track the stars, you must meet two criteria. First, you need a drive motor that moves at the same rate as the stars. The Celestron CM-1100 comes standard with a built-in drive motor designed specifically for this purpose. The second thing you need is to set the telescope's axis of rotation so that it tracks in the right direction. Since the motion of the stars across the sky is caused by the Earth's rotation about its axis, the telescope's axis must be made parallel to the Earth's.

Polar alignment is the process by which the telescope's axis of rotation (called the polar axis) is aligned (made parallel) with the Earth's axis of rotation. Once aligned, a telescope with a clock drive will track the stars as they move across the sky. The result is that objects observed through the telescope appear stationary (i.e., they will not drift out of the field of view). If not using the clock drive, all objects in the sky (day or night) will slowly drift out of the field. This motion is caused by the Earth's rotation. Even if you are not using the clock drive, polar alignment is still desirable since it will reduce the number of corrections needed to follow an object and limit all corrections to one axis (R.A.). There are several methods of polar alignment, all of which work on a similar principle, but performed somewhat differently. Each method is considered separately, beginning with the easier methods and working to the more difficult.

Although there are several methods mentioned here, you will never use all of them during one particular observing session. Instead, you may use only one if it is a casual observing session. Or, you may use two methods, one for rough alignment followed by a more accurate method if you plan on doing astrophotography.

Definition:

The polar axis is the axis around which the telescope rotates when moved in right ascension. This axis points the same direction even when the telescope moves in right ascension.

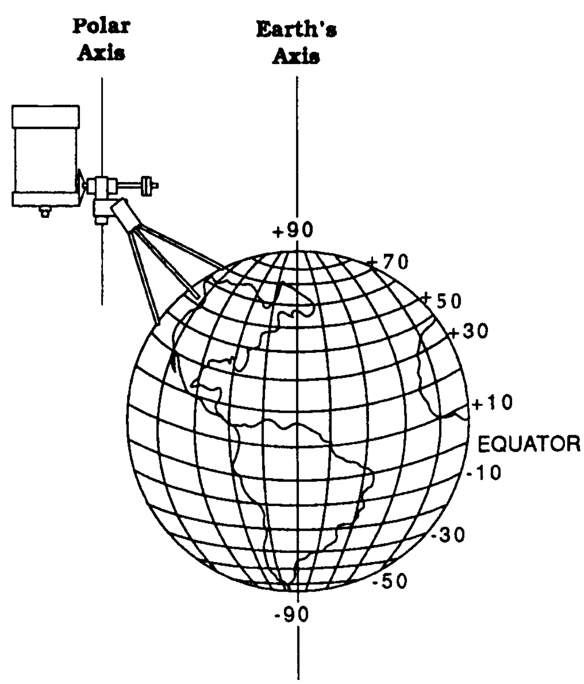

Figure 4-3

Download from Www.Somanuals.com. All Manuals Search And Download.

Finding the Pole

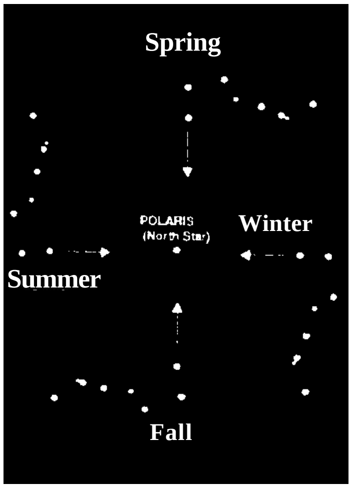

Figure 4-4

The position of the Big Dipper changes throughout the year and throughout the night.

In each hemisphere, there is a point in the sky around which all the other stars appear to rotate. These points are called the celestial poles and are named for the hemisphere in which they reside. For example, in the northern hemisphere all stars move around the north celestial pole. When the telescope's polar axis is pointed at the celestial pole, it is parallel to the Earth's rotational axis.

Many of the methods of polar alignment require that you know how to find the celestial pole by identifying stars in the area. For those in the northern hemisphere, finding the celestial pole is not too difficult. Fortunately, we have a naked eye star less than a degree away. This star, Polaris, is the end star in the handle of the Little Dipper. Since the Little Dipper (technically called Ursa Minor) is not one of the brightest constellations in the sky, it may be difficult to locate from urban areas. If this is the case, use the two end stars in the bowl of the Big Dipper (the pointer stars). Draw an imaginary line through them toward the Little Dipper. They point to Polaris. The position of the Big Dipper changes during the year and throughout the course of the night. When the Big Dipper is low in the sky (i.e., near the horizon), it may be difficult to locate.

Observers in the southern hemisphere are not as fortunate as those in the northern hemisphere. The stars around the south celestial pole are not nearly as bright as those around the north. The closest star that is relatively bright is Sigma Octantis. This star is just within naked eye limit (magnitude 5.5) and lies about 59 arc minutes from the pole. For more information about stars around the south celestial pole, please consult a star atlas.

Definition:

The north celestial pole is the point in the northern hemisphere around which all stars appear to rotate. The counterpart in the southern hemisphere is referred to as the south celestial pole.

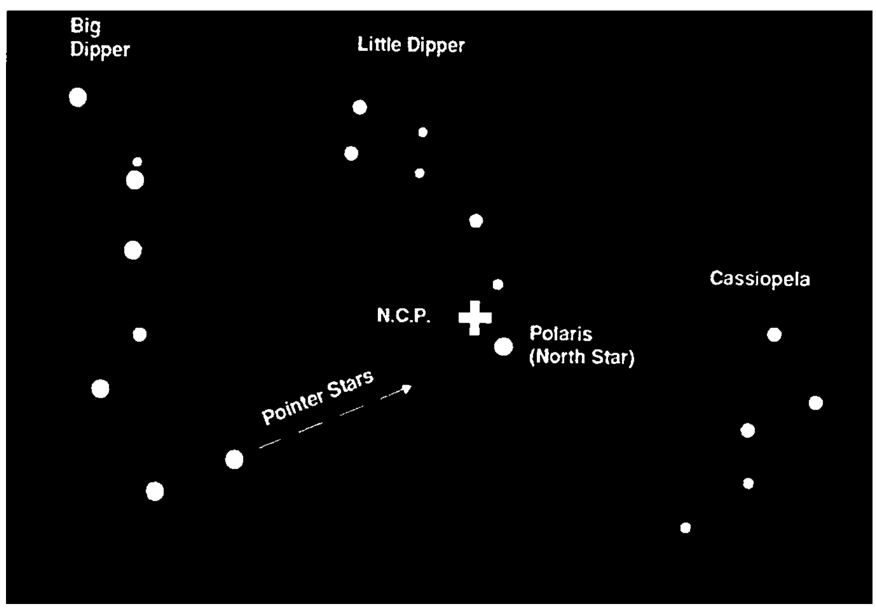

Figure 4-5

The two stars in the front of the bowl of the Big Dipper point to Polaris which is less than one degree from the true (north) celestial pole. Cassiopeia, the "W" shaped constellation is on the opposite side of the pole from the Big Dipper. The North Celestial Pole (N.C.P.) is marked by the "+" sign.

Download from Www.Somanuals.com. All Manuals Search And Download.

Latitude Scales

Figure 4-6

The altitude scale allows for settings between 13 and 65 degrees.

The easiest way to polar align a telescope is with a latitude scale. Unlike other methods that require you to find the celestial pole by identifying certain stars near it, this method works off of a known constant to determine how high the polar axis should be pointed. The Celestron CM-1100 mount can be adjusted from 13 to 65 degrees (see figure 4-6).

The constant, mentioned above, is a relationship between your latitude and the angular distance the celestial pole is above the northern (or southern) horizon; The angular distance from the northern horizon to the north celestial pole is always equal to your latitude. To illustrate this, imagine that you are standing on the north pole, latitude +90°. The north celestial pole, which has a declination of +90°, would be directly overhead (i.e., 90 above the horizon). Now, let's say that you move one degree south — your latitude is now +89° and the celestial pole is no longer directly overhead. It has moved one degree closer toward the northern horizon. This means the pole is now 89° above the northern horizon. If you move one degree further south, the same thing happens again. You would have to travel 70 miles north or south to change your latitude by one degree. As you can see from this example, the distance from the northern horizon to the celestial pole is always equal to your latitude.

If you are observing from Los Angeles, which has a latitude of 34°, then the celestial pole is 34° above the northern horizon. All a latitude scale does then is to point the polar axis of the telescope at the right elevation above the northern (or southern) horizon. To align your telescope:

1. Make sure the polar axis of the mount is pointing due north. Use a landmark that you know faces north.

2. Level the tripod. There is a bubble level built into the mount for this purpose.

NOTE: **Leveling the tripod is only necessary if using this method of polar alignment. Perfect polar alignment is still possible using other methods described later in this manual without leveling the tripod.**

3. Adjust the mount in altitude until the latitude indicator points to your latitude. Moving the mount affects the angle the polar axis is pointing. For specific information on adjusting the equatorial mount, please see the section "Adjusting the Mount."

This method can be done in daylight, thus eliminating the need to fumble around in the dark. Although this method does **NOT** put you directly on the pole, it will limit the number of corrections you will make when tracking an object. It will also be accurate enough for short exposure prime focus planetary photography (a couple of seconds) and short exposure piggyback astrophotography (a couple of minutes).

Download from Www.Somanuals.com. All Manuals Search And Download.

Pointing at Polaris

This method utilizes Polaris as a guidepost to the celestial pole. Since Polaris is less than a degree from the celestial pole, you can simply point the polar axis of your telescope at Polaris. Although this is by no means perfect alignment, it does get you within one degree. Unlike the previous method, this must be done in the dark when Polaris is visible.

1. Set the telescope up so that the polar axis is pointing north.

2. Loosen the DEC clutch knob and move the telescope so that the tube is parallel to the polar axis. When this is done, the declination setting circle will read +90°. If the declination setting circle is not aligned, move the telescope so that the tube is parallel to the polar axis.

3. Adjust the mount in altitude and/or azimuth until Polaris is in the field of view of the finder.

4. Center Polaris in the field of the telescope using the fine adjustment controls on the mount.

   Remember, while Polar aligning, do NOT move the telescope in R.A. or DEC. You do not want to move the telescope itself, but the polar axis. The telescope is used simply to see where the polar axis is pointing.

Like the previous method, this gets you close to the pole but not directly on it. The following methods help improve your accuracy for more serious observations and photography.

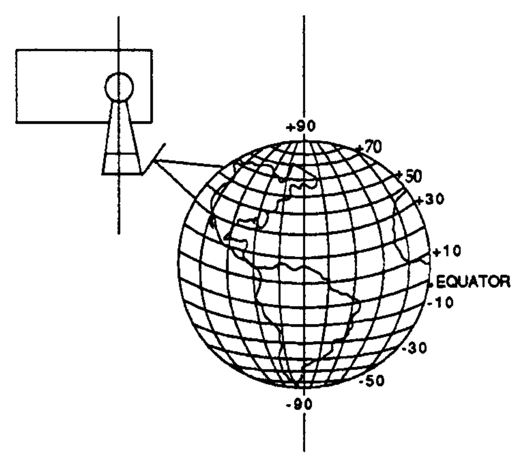

Figure 4-7

One might think that pointing at the pole produces a parallax effect, thus skewing the telescope's axis of rotation with that of the Earth's. Polaris, however, is over 50 light years away, thus making any parallax effect negligible. (One light year is 6.4 trillion miles. To find the distance to Polaris in miles, multiply 6.4 trillion by 50!)

Download from Www.Somanuals.com. All Manuals Search And Download.

The Polar Axis Finder

The Polar Axis Finder is designed to minimize polar alignment time while maintaining maximum accuracy. The installation of this accessory is described in the section on “Installing the Polar Axis Finder.”
Here’s how to use it:

1. Wait until it is dark enough to see Polaris with the unaided eye.

2. Place Polaris in the center of the crosshairs of the polar axis finder by adjusting the mounts latitude and azimuth controls (see figure 2-14 on page 16).

3. Rotate the polar scope until the small circle (located along the inner ring of the reticle) is positioned towards the celestial pole (see Figures 4-8 and 4-9). You may need to loosen the nylon tension screws on the polar finder bracket.

Remember that the north celestial pole is located by moving away from Polaris in the direction of the last star (Alkaid) in the handle of the Big Dipper .

4. Adjust the mount in altitude and azimuth until Polaris is in the small circle indicating the celestial pole.

When finished, the mount is accurately polar aligned.

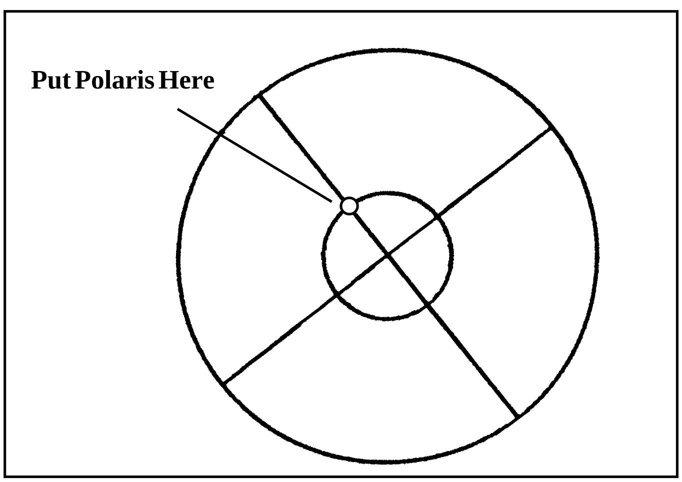

Figure 4-8

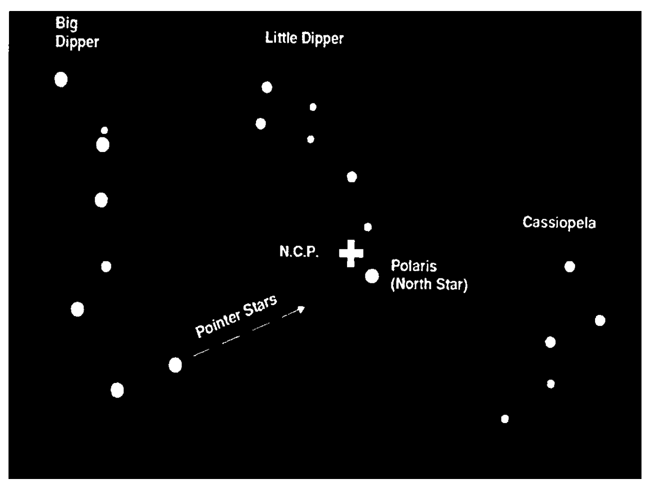

Figure 4-9

In this example the North Celestial Pole (NCP) is located approximately in the "11 O'clock" position relative to Polaris (Figure 4-9). Therefore, the polar finder reticle must be rotated to match the view as seen through the polar axis finder (Figure 4-8). Now, simply adjust the telescope's latitude and azimuth controls until Polaris is positioned in the small circle.

Download from Www.Somanuals.com. All Manuals Search And Download.

Declination Drift

This method of polar alignment allows you to get the most accurate alignment on the celestial pole and is required if you want to do long exposure deep-sky astrophotography through the telescope. The declination drift method requires that you monitor the drift of selected guide stars. The drift of each guide star tells you how far away the polar axis is pointing from the true celestial pole and in what direction. Although declination drift is quite simple and straight-forward, it requires a great deal of time and patience to complete when first attempted. The declination drift method should be done after any one of the previously mentioned methods has been completed.

To perform the declination drift method you need to choose two bright stars. One should be near the eastern horizon and one due south near the meridian. Both stars should be near the celestial equator (i.e., 0° declination). You will monitor the drift of each star one at a time and in declination only. While monitoring a star on the meridian, any misalignment in the east-west direction will be revealed. While monitoring a star near the east/west horizon, any misalignment in the north-south direction will be revealed. As for hardware, you will need an illuminated reticle ocular to help you recognize any drift. For very close alignment, a Barlow lens is also recommended since it increases the magnification and reveals any drift faster.

When looking due south with the scope on the side of the mount, insert the diagonal so it points straight up. Insert a cross hair ocular and align the cross hairs to be parallel to declination and right ascension motion. Use ± 16x guide setting to check parallelism.

First choose your star near where the celestial equator and the meridian meet. The star should be approximately ±1/2 hour of the meridian and ±5 degrees of the celestial equator. Center the star in the field of your telescope and monitor the drift in declination.

- If the star drifts south, the polar axis is too far east.
- If the star drifts north, the polar axis is too far west.

Make the appropriate adjustments to the polar axis to eliminate any drift. Once you have managed to eliminate all drift, move to the star near the eastern horizon. The star should be 20 degrees above the horizon and ± 5 degrees of the celestial equator.

- If the star drifts south, the polar axis is too low.
- If the star drifts north, the polar axis is too high.

Once again, make the appropriate adjustments to the polar axis to eliminate any drift. Unfortunately, the latter adjustments interact with the prior adjust-ments ever so slightly. So, repeat the process again to improve the accuracy checking both axes for minimal drift. Once the drift has been eliminated, the telescope is very accurately aligned. You will now be able to do prime focus deep-sky astrophotography for long periods.

NOTE: If the eastern horizon is blocked, you may choose a star near the western horizon. However, you will have to reverse the polar high/low error directions. If using this method in the southern hemisphere, the procedure is the same as described above. However, the direction of drift is reversed.

Download from Www.Somanuals.com. All Manuals Search And Download.

Aligning the R.A. Setting Circle

Before you can use the setting circles to find objects in the sky, you need to align both the R.A. and DEC setting circles. In order to align the setting circle, you need to know the names of a few of the brightest stars in the sky. If you don't, they can be learned by using the Celestron Sky Maps (#93722) or consulting a current astronomy magazine. To align the R.A. setting circle:

1. Locate a bright star near the celestial equator. The farther you are from the celestial pole, the better your reading of the R.A. setting circle. The star you choose to align the setting circle with should be a bright one whose coordinates are known and easy to look up. (For a list of bright stars to align the R.A. setting circle, see the list at the back of this manual.)

2. Center the star in the finder.

3. Center the star in the field of the telescope.

4. Start the clock drive so that the mount tracks the star.

5. Look up the coordinates of the star. You can consult a star catalog or use the list at the end of this manual.

6. Rotate the circle until the proper coordinates line up with the R.A. indicator. The R.A. setting circle should rotate freely. The R.A. setting circle has a marker every four minutes with each hour labeled (see figure 4-10).

The R.A. setting circle is now aligned and ready to use. The R.A. setting circle is clutched to the R.A. gear rotation. As long as the R.A. drive is operating, the circle does not need to be reset once indexed to the correct coordinate (i.e., once aligned). If the drive is ever turned off, then the R.A. setting circle must be reset once activated. While the R.A. setting circle tracks with the drive motor, it does not move when slewing the telescope.

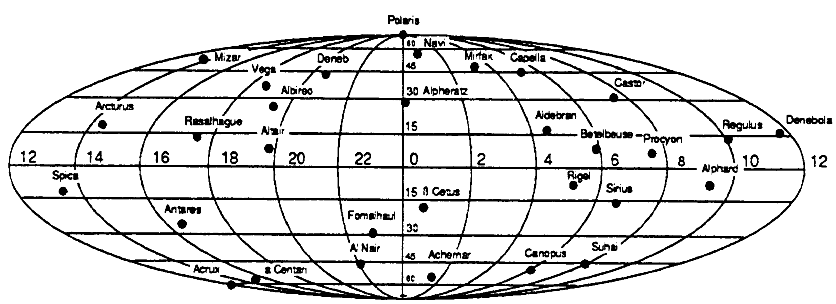

Figure 4-10

Setting the DEC Circle

The declination setting circle is fixed in place and cannot be moved be hand. Once the mount is polar aligned with the DEC circle reading 90°, simply move the telescope in declination until the desired coordinance are reached.

Download from Www.Somanuals.com. All Manuals Search And Download.

The drive system uses a 5.625 diameter bronze gear with 180 teeth for incredibly accurate tracking. One of the most unique features of the drive is the Periodic Error Correction (PEC) function. This feature allows the drive system to “learn” the characteristics of the worm gear, and as a result, improve the tracking accuracy even more. This typically reduces the periodic error to 30 percent or less of the original error. The amount of improvement varies depending on guiding skill, atmospheric stability, the characteristics of the worm gear, and the accuracy of polar alignment.

Following is a brief discussion of each feature.

Powering Up the Drive

In order to activate the drive, you must first plug it into an external power source. To supply power to your Celestron CM-1100, plug your Car Battery Adapter or optional AC Adapter into the outlet on the electronic console labeled “12 VDC.” Then, plug the other end of the adapter into the appropriate power source (i.e., either AC or DC depending on the adapter used).

Next, plug the R.A. and DEC cables into the electronic box. The DEC cable has a modular phone jack connector on each end. Plug one end into the DEC Motor receptacle on the electronics console and the other end into the declination motor. The R.A. cable has a modular phone jack connector at one end and a 5-pin connector at the other end. Attach the 5-pin connector over the 5 pins at the top of the electronics module (labled R.A. Motor), and then plug the phone jack connector into the R.A. motor.

Once plugged into the proper power source, activate the drive by placing the ON/OFF switch in the “ON” position. Once activated, the drive begins tracking at sidereal rate, the default tracking rate. The LED next to the sidereal rate icon will illuminate.

Figure 5-1

The CI-700 electronic console.

Download from Www.Somanuals.com. All Manuals Search And Download.

Guide Speed

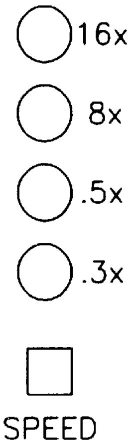

Figure 5-2

This function allows you to select the speed at which the motor moves when corrections are made via the hand controller. Once the drive is activated, the default setting is .3 times sidereal rate. Press the Speed button to change the guiding rate. The selections are .3x, .5x, 8x, and 16x sidereal rate.

For guiding, use either the .3x or .5x setting. These two rates allow optimal use with autoguiders. The faster settings — 8x and 16x — are perfect for positioning objects within the field of view.

The telescope can also move at 20x speed WITHOUT changing any of the guide settings. To control the telecope at 20x speed, press the button that corresponds to the direction you want to move the telescope. While holding the button down, press the opposite directional button. For example, if you want to move the telescope west, hold the west button down and then press the east button. Conversely, if you want to move the telescope east, hold the east button down and then press the west button. This "fast-set" function also works in declination. It should be noted that the R.A. setting circle does not remain calibrated when using any of the slewing rates.

NOTE: If the 20x speed is not functioning (but all other speeds do), it is probably due to low voltage from your power source.

Tracking Rate Selection

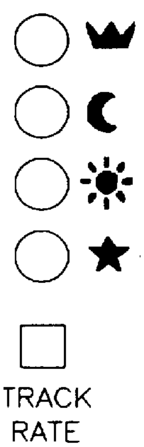

Figure 5-3

The drive has four basic rates: sidereal, solar, lunar and King (which is a modified sidereal rate that takes into account atmospheric refraction). While solar and lunar rates are obvious, sidereal and King rates require a little more explaining. Sidereal rate is based on a single rotation of the Earth which takes 1,436.5 minutes. An astronomer by the name of King discovered that atmospheric refraction affects the apparent motion of objects across the sky. The King rate takes into account this refraction caused by the Earth's atmosphere and is recommended for deep-sky astrophotography. For deep-sky observing, either King or sidereal rate is fine.

Each of the tracking rates is represented by an icon. Sidereal rate is represented by a star ( ), solar rate by a sun ( ), lunar rate by a crescent moon ( ) and King rate by a crown ( ) . Next to each icon is an LED to indicate which rate has been selected. Once the power has been turned on, the drive tracks at sidereal rate, the default tracking rate. To change the tracking rate, press the "TRACK RATE" button. Pressing the button once changes the drive rate once. The rates are selected sequentially from bottom-to-top as listed above.

Note that the PEC function does **NOT** have to be activated for the drive to work. However, once PEC is activated, the drive rate is locked on the one selected. You can not change rates until PEC is turned off.

Download from Www.Somanuals.com. All Manuals Search And Download.

BC — Backlash Correction

The BC (Backlash Correction) function allows you to eliminate the backlash in the DEC motor when changing directions (i.e., from north to south or vice versa). Here's how it works. Each time you change the direction of the telescope in declination, the motor speeds up momentarily to take up any slack. The Tracking Rate and Guide Speed displays are used to regulate the "aggressiveness" of the backlash compensation. The best setting is determined by looking through the eyepiece while changing the direction of the DEC motor and then moving through the BC button settings until the backlash has been eliminated.

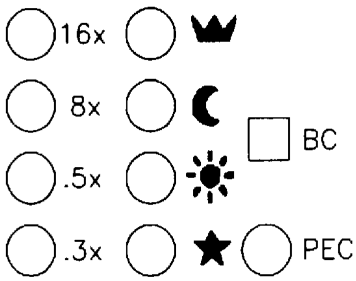

Figure 5-4—The guide rate and tracking rate lights are used to indicate the amount of backlash correction.

To activate this function, press the BC button. Once activated, the .3x guide speed and sidereal tracking LED will flash rapidly. Use the east and west (left and right) buttons on the hand control to change the backlash compensation speed. Press the right hand control button and the next guide speed light (.5x) will illuminate. When the hand control button is pressed four times, the next tracking rate light ( ) will illuminate. Continue pressing the hand control buttons until the desired compensation speed is reached or until you reach the highest setting (16x and). Once the desired level is set, press the BC button again to activate backlash correction. The BC must be reset each time you power up the drive.

Periodic Error Correction (PEC)

Periodic Error Correction, or PEC for short, is a system that improves the tracking accuracy of the drive. PEC is designed to improve photographic quality by reducing the amplitude of the worm errors. Using the PEC function is a two-step process. First, you must guide for at least eight minutes — keeping the guide star centered on the cross hairs of your optional guiding eyepiece — during which time the system records the corrections you make. (It takes the worm gear eight minutes to make one complete revolution, hence the need to guide for eight minutes). The second step is to play back the corrections you made during the recording phase. The microcomputer inside the electronic console does this automatically after one revolution of the worm gear.

Definition:

Periodic error is a slight oscillation in right ascension caused by imperfections in all drive gears. The cycle of the periodic error is equal to the rotation of the [worm] gear, in this case eight minutes. All telescope drives with gears have some periodic error. The periodic error of your Celestron CM-1100 is very slight to begin with.

Keep in mind, this feature is for advanced astrophotographers and requires careful guiding. Here's how to use the PEC function most effectively.

1. Find a bright star relatively close to the object you want to photograph.

2. Insert a high power eyepiece with illuminated cross hairs into your telescope. Orient the guiding eyepiece cross hairs so that one is parallel to the declination axis while the other is parallel to the R.A. axis.

3. Center the guide star on the illuminated cross hairs, focus the telescope, and study the periodic movement.

4. Take a few minutes to practice guiding. This will help you familiarize yourself with the periodic error of the drive and the operation of the hand control box.

Download from Www.Somanuals.com. All Manuals Search And Download.

5. Press the “PEC” button once to activate the mode. The LED will flash once a second for 5 seconds indicating you have five seconds to get back to the eyepiece and begin guiding before it begins recording. The .3x guiding rate is best for this function.

NOTE: **The star should stay centered on the cross hairs for a few seconds without using the hand controller before activating the PEC function.**

6. Guide for eight minutes. Try not to overshoot corrections in right ascension. Ignore drift in declination. During the record phase, the LED flashes a little faster.

After eight minutes, the system begins to play back the corrections made during the first eight minutes. When playing back, the LED stays on without blinking.

NOTE: If you press the PEC button while it is in playback mode, you will lose the previously recorded information. Also, the fast slew functions are locked while the PEC function is activated. This eliminates the possibility of shifting the focus or moving the telescope suddenly during an exposure.

The fast-set function is locked while the PEC function is activated. This eliminates the possibility of moving the telescope suddenly during an exposure.

Once you have used the PEC function for awhile you may mistake its operation for the way the drive normally operates. The best way to see how well the PEC function works is to turn it off. PEC results improve with practice and patience.

HC/CCD

This outlet accepts the hand controller needed for guiding and moving the telescope. This outlet uses a modular phone-type jack. Push the connector on the cable into the outlet until the plastic tab clicks. To remove the cable, squeeze the plastic tab and pull away from the outlet.

12 V DC

This outlet is used to supply power to the telescope. Your Celestron CM-1100 comes standard with a Car Battery Adapter. To install the adapter, plug the connector into the electronic console first, then the power source (automobile cigarette lighter receptacle).

Download from Www.Somanuals.com. All Manuals Search And Download.

Northern/Southern Hemisphere Operation

When using your Celestron CM-1100 in the southern hemisphere, there is a need to reverse the motors. Changing from northern hemisphere to southern hemisphere requires changing the polarity of the drive motor by changing the settings of the dip switches on the electronics board. To do this:

1. Remove the cover of the electronic console by removing the four screws (one in each corner).

2. Remove the two screws (one directly above the DEC motor jack and the other next to the On/Off indicator light) that attach the cover to the electronics board where the dip switches are located.

3. Locate the dip switches on the electronics board as shown on figure 5-5.

4. For operation in the southern hemisphere, set switch 4 to the OFF or down position (see Figure 5-6).

The direction of the drive motor is now reversed and will work in the southern hemisphere. If going from the southern hemisphere to the northern hemisphere, simply change the switch back to the ON or up position.

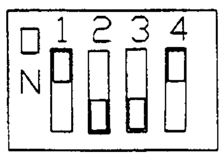

Figure 5-5

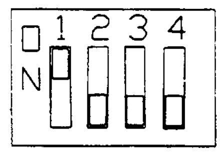

Figure 5-6

The Hand Controller

The hand controller allows you to move the telescope in R.A. and DEC using the corresponding motors. This includes fine corrections for guided astrophotography and minor adjustments for centering objects in the field of view.

The buttons on the hand controller are intentionally labeled in a rather vague manner. This is due to the fact that the direction of motion of the mount varies depending on how the telescope is oriented. Furthermore, these buttons are user definable to eliminate confusion when guiding. (For more information, see the section on "R.A./DEC Reverse.")

Once again, to move the telescope at the 20x speed **WITHOUT** changing the guide setting, press the button that corresponds to the direction you want to move the telescope. While holding the button down, press the opposite directional button. For example, if you want to move the telescope west, hold the west button down and then press the east button. Conversely, if you want to move the telescope east, hold the east button down then press the west button. The fast-set function also works in declination.

Download from Www.Somanuals.com. All Manuals Search And Download.

R.A./DEC Reverse

As mentioned previously, the direction a particular button moves the mount varies depending on the telescope’s orientation (i.e., whether it’s on the east or west side of the mount). This can create confusion when guiding if you change the telescope’s orientation during a given photographic session. To compensate for this, the direction of the R.A. and DEC buttons are changeable. To reverse the direction of either the R.A. and/or DEC buttons, change the switch setting of the appropriate axis (see Figure 5-7).

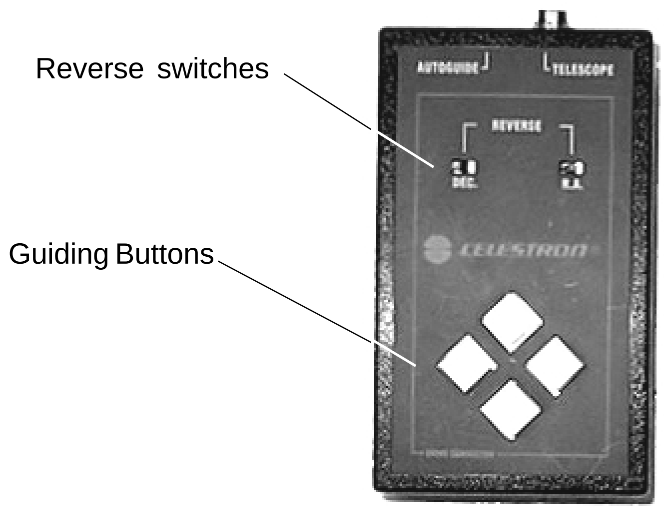

Figure 5-7

Autoguiding

On the top side of the hand controller you will find a phone jack outlet designated for use with an autoguider. Most CCD autoguiders will require a cable that attaches the autoguider to your telescope's drive controller via the hand controller outlet, rendering the hand controller inoperable. By plugging the autoguider cable directly into the hand controller, you have the ability to override the autoguider and make manual corrections with the hand controller buttons.

Download from Www.Somanuals.com. All Manuals Search And Download.

With your telescope set up, you are ready to use it for observing. This section covers visual observing of both solar system and deep-sky objects.

Observing the Moon

In the night sky, the Moon is a prime target for your first look because it is extremely bright and easy to find. Often, it is a temptation to look at the Moon when it is full. At this time, the face we see is fully illuminated and its light can be overpowering. In addition, little or no contrast can be seen during this phase.

One of the best times to observe the Moon is during its partial phases (around the time of first or third quarter). Long shadows reveal a great amount of detail on the lunar surface. At low power you will be able to see most of the lunar disk at one time. The optional Reducer/Corrector lens allows for breathtaking views of the entire lunar disk when used with a low power eyepiece. Change to higher power (magnification) to focus in on a smaller area. Keep in mind that if you are not using the clock drive, the rotation of the Earth will cause the Moon to drift out of your field of view. You will have to manually adjust the telescope to keep the Moon centered. This effect is more noticeable at higher power. If you are using the clock drive and have polar aligned, the Moon will remain centered if using the lunar tracking rate. Consult your local newspaper or a current astronomy magazine to find out when the Moon will be visible.

LUNAR OBSERVING HINTS

- To ensure accurate tracking, be sure to select the lunar tracking rate.
- Try using eyepiece filters to increase contrast and bring out more detail on the lunar surface.

Observing the Planets

Other easy targets in the night sky include the five naked eye planets. You can see Venus go through its lunar-like phases. Mars can reveal a host of surface detail and one, if not both, of its polar caps. You will be able to see the cloud belts of Jupiter and the great Red Spot (if it is visible at the time you are observing). In addition, you will also be able to see the moons of Jupiter as they orbit this gas giant. Saturn, with its beautiful rings, is easily visible at moderate power. All you need to know is where to look. Most astronomy publications tell where the planets can be found in the sky each month.

King or sidereal rates work best for tracking the planets.

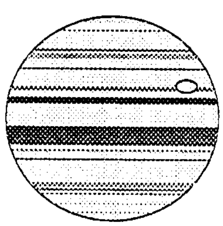

Figure 6-1

This scanned drawing of Jupiter provides a good representation of what you can expect to see with moderate magnification during good seeing conditions.

Download from Www.Somanuals.com. All Manuals Search And Download.

Observing the Sun

Although overlooked by many amateur astronomers, solar observation is both rewarding and fun. However, because the Sun is so bright, special precautions must be taken when observing our star so as not to damage your eyes or your telescope.

WARNING:

Never project an image of the Sun through the telescope. Because of the folded optical design, tremendous heat buildup will result inside the optical tube. This can damage the telescope and/or any accessories attached to the telescope.

For safe solar viewing, use a solar filter. These filters reduce the intensity of the Sun's light, making it safe to view. With these filters you can see sunspots as they move across the solar disk and faculae, which are bright patches seen near the Sun's edge. **Be sure to cover the lens of the finder or completely remove the finder when observing the Sun. This will ensure that the finder itself is not damaged and that no one looks through it inadvertently.**

SOLAR OBSERVING HINTS

- The best time for observing the Sun is in the early morning or late afternoon when the air is cooler.
- To locate the Sun without a finder, watch the shadow of the optical telescope tube until it forms a circular shadow.
- To ensure accurate tracking, be sure to select the solar tracking rate.

Download from Www.Somanuals.com. All Manuals Search And Download.

Observing Deep-Sky Objects

Deep-sky objects are simply those objects outside the boundaries of our solar system. They include star clusters, planetary nebulae, diffuse nebulae, double stars, and other galaxies outside our own Milky Way. The Celestron Sky Maps (#93722) can help you locate the brightest deep-sky objects. You can use your setting circles or "star hop" to an object from an area with which you are familiar.

Most deep-sky objects have a large angular size. Therefore, low-to-moderate power is all you need to see them. Visually, they are too faint to reveal any color seen in long exposure photographs. Instead, they have a black and white appearance. And, because of their low surface brightness, they should be observed from a dark sky location. Light pollution around large urban areas washes out most nebulae making them difficult, if not impossible, to observe. Light Pollution Reduction filters help reduce the background sky increasing contrast.

Using Your Setting Circles

Once the setting circles are aligned you can use them to find any object with known coordinates.

1. Select an object to observe. Use a seasonal star chart or planisphere to make sure the object you chose is above the horizon. As you become more familiar with the night sky, this will no longer be necessary.
2. Look up the coordinates in an atlas or reference book.
3. Move the telescope in declination until the indicator is pointing at the correct declination coordinate.
4. Move the telescope in R.A. until the indicator points to the correct coordinate (do NOT move the R.A. circle). The telescope will track in R.A. as long as the clock drive is operating.
5. Look through the finder to see if you have located the object.
6. Center the object in the finder.
7. Look in the main optics using a low power eyepiece; the object should be there.
8. Repeat the process for each object observed throughout the observing session.

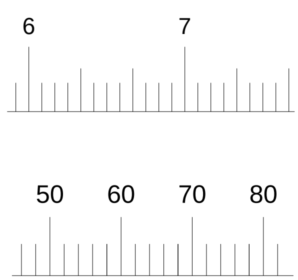

Figure 6-2

The R.A. setting circle (top) and the DEC circle (bottom).

You may not be able to see fainter objects in the finder. When this happens, gradually sweep the telescope around until the object is visible.

The declination setting circle is scaled in degrees while the R.A. setting circle is incremented in minutes with a marker every five minutes (see figure 6-2). As a result, the setting circles will get you close to your target, but not directly on it. Also, the accuracy of your polar alignment will also affect how accurately your setting circles read. It should be noted that the R.A. setting circle does not remain calibrated when using any of the slewing rates.

At the end of this manual there is a list of deep-sky objects well within reach of your Celestron CM-1100 telescope.

Download from Www.Somanuals.com. All Manuals Search And Download.

Star Hopping

Another way to find deep-sky objects is by star hopping. Star hopping is done by using bright stars to “guide” you to an object. Here are the directions for two popular objects.

The Andromeda Galaxy, M31, is an easy target. To find M31:

1. Locate the constellation of Pegasus, a large square visible in the fall and winter months.
2. Start at the star in the northeast corner. The star is Alpha (α) Andromedae.
3. Move northeast approximately 7°. There you will find two stars of equal brightness — Delta (δ) and Pi (π) Andromedae — about 3° apart.
4. Continue in the same direction another 8°. There you will find two stars — Beta (β) and Mu (μ) Andromedae — about 3° apart.
5. Move 3° northwest — the same distance between the two stars — to the Andromeda galaxy. It is easily visible in the finder.

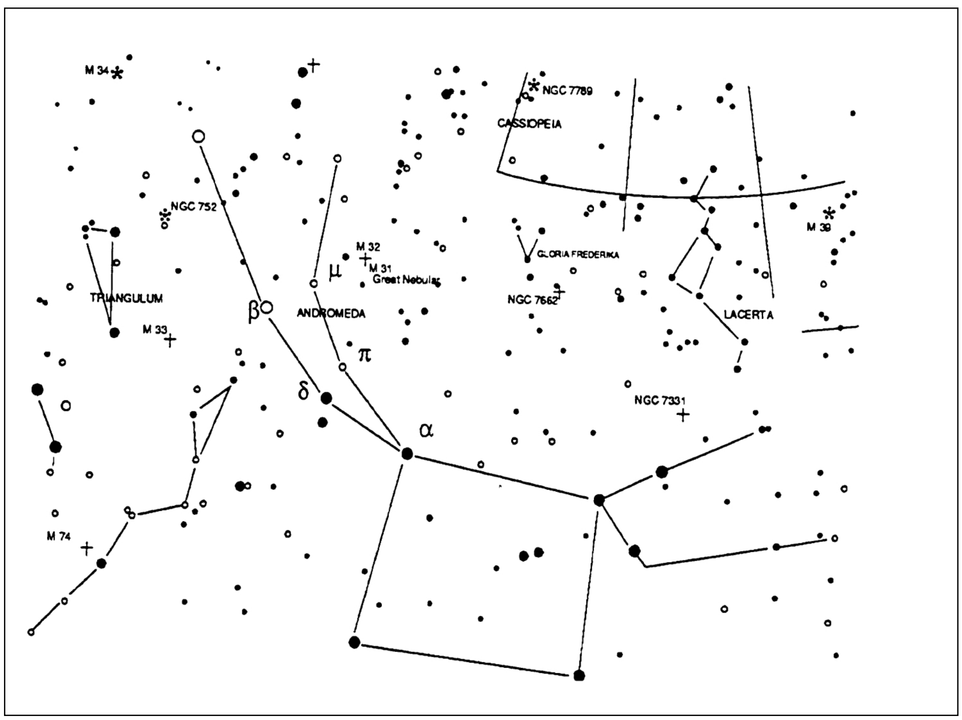

Figure 6-3

Star hopping to the Andromeda Galaxy is a snap to find since all the stars needed to do so are visible to the naked eye. Note that the scale for this star chart is different from the one on the following page which shows the constellation Lyra.

Download from Www.Somanuals.com. All Manuals Search And Download.

Star hopping may take some getting used to since you can see more stars through the finder than you can see with the naked eye. And, some objects are not visible in the finder. One such object is M57, the famed Ring Nebula. Here's how to find it:

1. Find the constellation of Lyra, a small parallelogram visible in the summer and fall months. Lyra is easy to pick out because it contains the bright star Vega.

2. Start at the star Vega — Alpha (α) Lyrae — and move a few degrees southeast to find the parallelogram. The four stars that make up this geometric shape are all similar in brightness making them easy to see.

3. Locate the two southernmost stars that make up the parallelogram — Beta (β) and Gamma (γ) Lyrae.

4. Point the finder half way between these two stars.

5. Move about 1/2° toward Beta (β) Lyrae, but remaining on a line that connects the two stars.

6. Look through the telescope and the Ring Nebula should be in the telescope. Its angular size is quite small and, therefore, not visible in the finder.

Because the Ring Nebula is rather faint, you may need to use averted vision to see it. Averted vision is the act of looking slightly away from the object you are observing. So, if you are observing the Ring Nebula, center it in the field of view and then look off toward the side. In this manner, light from the object is falling on the black and white sensitive rods as opposed to the color sensitive cones. These two examples should give you an idea of how to star hop to deep-sky objects. To use this method on other objects, consult any of the star atlases and star hop to the object of your choice using naked eye stars.

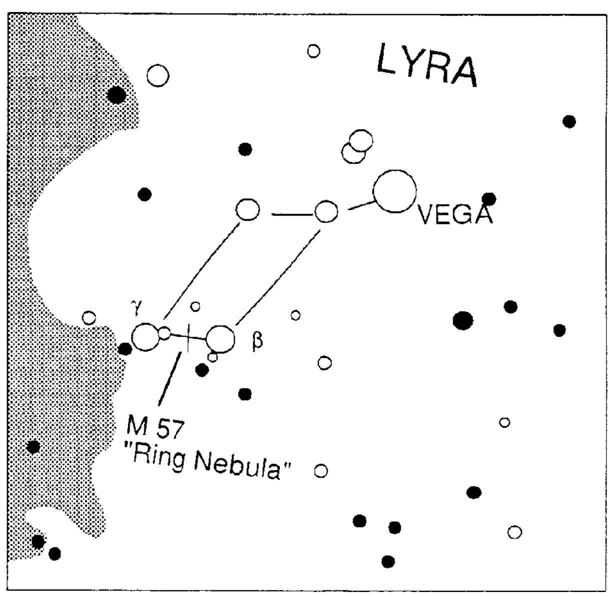

Figure 6-4

Although the Ring Nebula lies between two naked eye stars, it may take a little time to locate since it is not visible in the finder. Note that the scale for this star chart is different from the one on the previous page which shows several constellations including Pegasus, Triangulum, and Andromeda.

Download from Www.Somanuals.com. All Manuals Search And Download.

Viewing Conditions

Viewing conditions affect what you can see through your CM-1100 telescope during an observing session. Conditions include transparency, sky illumination, and seeing. Understanding viewing conditions and the effect they have on observing will help you get the most out of your CM-1100 telescope.

Transparency

Transparency is the clarity of the atmosphere and is affected by clouds, moisture, and other airborne particles. Thick cumulus clouds are completely opaque while cirrus clouds can be thin, allowing the light from the brightest stars through. Hazy skies absorb more light than clear skies making fainter objects harder to see and reducing contrast on brighter objects. Aerosols ejected into the upper atmosphere from volcanic eruptions also affect transparency. Ideal conditions are when the night sky is inky black.

Sky Illumination

General sky brightening caused by the Moon, aurorae, natural airglow, and light pollution greatly affect transparency. While not a problem for the brighter stars and planets, bright skies reduce the contrast of extended nebulae making them difficult, if not impossible, to see. To maximize your observing, limit deep-sky viewing to moonless nights far from the light polluted skies found around major urban areas. You can, on the other hand, observe planets and stars from light polluted areas or when the Moon is out.

Seeing Conditions

Seeing conditions refer to the stability of the atmosphere and directly effects the clarity of star images and the amount of fine detail seen in extended objects. The air in our atmosphere acts as a lens which bends and distorts incoming light rays. The amount of bending depends on air density. Varying temperature layers have different densities and therefore bend light differently. Light rays from the same object arrive slightly displaced creating an imperfect or smeared image. These atmospheric disturbances vary from time-to-time and place-to-place. The size of the air parcels compared to your aperture determines the “seeing” quality. Under good seeing conditions, fine detail is visible on the brighter planets like Jupiter and Mars, and stars are pinpoint images. Under poor seeing conditions, images are blurred and stars appear as blobs. Seeing conditions are rated on a five-point scale where one is the worst and five is the best (see figure 6-5). Seeing conditions can be classified in one of three categories.

Type 1 seeing conditions are characterized by rapid changes in the image seen through the telescope. Extended objects, like the Moon, appear to shimmer while point sources (i.e., stars) appear double. Type 1 seeing is caused by currents within or very close to the telescope tube. These currents could be caused by a telescope that has not reached thermal equilibrium with the outdoor surroundings, heat waves from people standing near the telescope, or heated dew caps. To avoid the problems associated with Type 1 seeing, allow your telescope at least 45 minutes to reach thermal equilibrium. Once adjusted to the outdoor temperature, don’t touch the telescope tube with your hands. If observing with others, make sure no one stands in front of or directly below the telescope tube.

Download from Www.Somanuals.com. All Manuals Search And Download.

Type 2 seeing conditions do move as quickly as Type 1, though the image is quite blurry. Fine detail is lost and the contrast is low for extended objects. Stars are spread out and not sharp. The source of Type 2 seeing is the lower atmosphere, most likely heat waves from the ground or buildings. To avoid the problems associated with Type 2 seeing, select a good observing site. Specifically, avoid sites that overlook asphalt parking lots or ploughed fields. Stay away from valleys and shorelines. Look for broad hilltops or open grassy fields. Stable thermal conditions found near lakes and atmospheric inversions also tend to produce good seeing. If you can't get a better location, wait until the early morning hours when the surroundings are uniformly cool and the seeing is generally better.

Type 3 seeing conditions are characterized by fast ripples, but sharp images. In extended objects fine detail is visible, but the image shifts around the field. Stars are crisp points, but they shift small distances rapidly around the field. The cause of Type 3 seeing is turbulence in the upper atmosphere which means the observer has less control over it. However, the effects of Type 3 seeing are generally less pronounced that the other two types. You can never really avoid Type 3 seeing. Your best bet is to wait until moments of steadiness. If the seeing is extremely bad, pack up and wait for a better night.

The conditions described here apply to both visual and photographic observations.

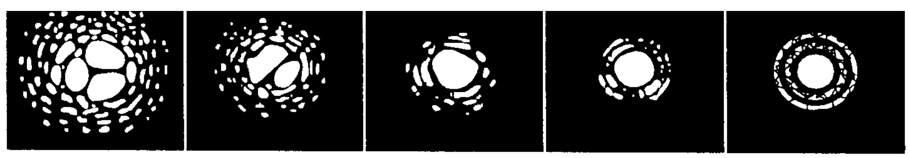

Figure 6-5

Seeing conditions directly affect image quality. These drawings represent a point source (i.e., star) under bad seeing conditions (left) to excellent conditions (right). Most often, seeing conditions produce images that lie some where between these two extremes.

CELESTIAL PHOTOGRAPHY

After looking at the night sky for awhile you may want to try photographing it. Several forms of celestial photography are possible with your Celestron CM-1100 telescope. The most common forms of celestial photography, in order of difficulty are; short exposure prime focus, piggyback, eyepiece projection, and long exposure deep-sky. Each of these is discussed in moderate detail with enough information to get you started. Topics include the accessories required and some simple techniques. More information is available in some of the publications listed at the end of this manual.

In addition to the specific accessories required for each type of celestial photography, there is the need for a camera — but not just any camera. The camera does not need many of the features offered on today's state-of-the-art equipment. For example, you don't need auto focus capability or mirror lock-up. Here are the mandatory features a camera needs for celestial photography. First, a 'B' setting which allows for time exposures. This excludes point and shoot cameras and limits the selection to SLR cameras, the most common type of 35mm camera on the market today.

Second, the 'B' or manual setting should not run off the battery. Many new electronic cameras use the battery to keep the shutter open during time exposures. Once the batteries are drained, usually after a few minutes, the shutter closes, whether you were finished with the exposure or not. Look for a camera that has a manual shutter when operating in the time exposure mode. Olympus, Nikon, Minolta, Pentax and others have made such camera bodies.

The camera should have interchangeable lenses so you can attach it to the telescope and so you can use a variety of lenses for piggyback photography. If you can't find a new camera, you can purchase a used camera body that is not 100-percent functional. The light meter does not have to be operational since you will be determining the exposure length manually.

A cable release is needed with a locking function to hold the shutter open while you do other things. Mechanical and air releases are available.

Is unguided astrophotography possible? Yes and no. For solar (filtered), lunar, and piggyback (up to 200mm telephotos), the answer is yes. However, even with PEC, off-axis guiding is still mandatory for long exposure, deep-sky astrophotography. The Reducer/Corrector lens reduces exposure times making the task of guiding a little easier.

Download from Www.Somanuals.com. All Manuals Search And Download.

Short Exposure Prime Focus

Short exposure prime focus photography is the best way to begin recording celestial objects. It is done with the camera attached to the telescope without an eyepiece or camera lens in place. To attach your camera you need the Celestron T-Adapter (#93633-A) and a T-Ring for your specific camera (i.e., Minolta, Nikon, Pentax, etc.). The T-Ring replaces the 35mm SLR camera's normal lens. Prime focus photography allows you to capture the majority of the solar disk (if using the proper filter) as well as the Moon. To attach your camera to your CM-1100:

1. Remove all visual accessories.

2. Thread the T-Ring onto the T-Adapter.

3. Mount your camera body onto the T-Ring the same as you would any other lens.

4. Thread the T-Adapter onto the back of the Celestron CM-1100 while holding the camera in the desired orientation (either vertical or horizontal).

With your camera attached to the telescope, you are ready for prime focus photography. Start with an easy object like the Moon. Here's how to do it:

1. Load your camera with film that has a moderate-to-fast speed (i.e., ISO rating). Faster films are more desirable when the Moon is a crescent. When the Moon is near full, and at its brightest, slower films are more desirable. Here are some film recommendations:

    - T-Max 100
    - T-Max 400
    - Any 100 to 400 ISO color slide film
    - Fuji Super HG 400

2. Center the Moon in the field of your CM-1100

3. Focus the telescope by turning the focus knob until the image is sharp.

4. Set the shutter speed to the appropriate setting (see the table below).

5. Trip the shutter using a cable release.

6. Advance the film and repeat the process.

Lunar Phase	ISO 50	ISO 100	ISO 200	ISO 400
Crescent	1/2	1/4	1/8	1/15
Quarter	1/15	1/30	1/60	1/125
Full	1/30	1/60	1/125	1/125

Table 7-1

Above is a listing of recommended exposure times when photographing the Moon at the prime focus of your Celestron CM-1100 telescope.

Download from Www.Somanuals.com. All Manuals Search And Download.

The exposure times listed here should be used as a starting point. Always make exposures that are longer and shorter than the recommended time. Also, try bracketing your exposures, taking a few photos at each shutter speed. This will ensure that you will get a good photo.

Keep accurate records of your exposures. This information is useful if you want to repeat your results or if you want to submit some of your photos to various astronomy magazines for possible publication!

This same technique is used for photographing the Sun with the proper solar filter.

Download from Www.Somanuals.com. All Manuals Search And Download.

Piggyback

The easiest way to enter the realm of deep-sky, long exposure astrophotography is via the piggyback method. Piggyback photography is done with a camera and its normal lens riding on top of the telescope. Through piggyback photography you can capture entire constellations and record large scale nebulae that are too big for prime focus photography. Because you are photographing with a low power lens and guiding with a high power telescope, the margin for error is very large. Small mistakes made while guiding the telescope will not show up on film. Use the optional piggyback mount to attach the camera to the telescope.

As with any form of deep-sky photography, you must be at a dark sky observing site. Light pollution around major urban areas washes out the faint light of deep-sky objects.

1. Polar align the telescope (using one of the methods described earlier) and start the clock drive.

2. Load your camera with slide film, ISO 100 or faster, or print film, ISO 400 or faster!

3. Set the f/ratio of your camera lens so that it is a half stop to one full stop down from completely open.

4. Set the shutter speed to the "B" setting and focus lens to infinity setting.

5. Locate the area of the sky that you want to photograph and move the telescope so that it points in that direction.

6. Find a suitable guide star in the telescope field. This is relatively easy since you can search a wide area without affecting the area covered by your camera lens. If you do not have an illuminated cross hair eyepiece for guiding, simply defocus your guide star until it fills most of the field of view. This makes it easy to detect any drift.

7. Release the shutter using a cable release.

8. Monitor your guide star for the duration of the exposure. Make all corrections using the hand controller.

9. Close the camera's shutter.

As for lenses, get good ones that produce sharp images near the edge of the field. Generally, stay away from generic lenses. The lenses should have a resolving power of 40 lines per millimeter. A good focal length range is 35 to 100mm for lenses designed for 35mm cameras.

Download from Www.Somanuals.com. All Manuals Search And Download.

The exposure time depends on the film being used. However, five minutes is usually a good starting point. With slower films, like 100 ISO, you can expose as long as 45 minutes. With faster films, like 1600 ISO, you really shouldn't expose more than 5 to 10 minutes. When getting started, use fast films to record as much detail in the shortest possible time. Here are proven recommendations:

- Ektar 1000 (color print)
- Konica 3200 (color print)
- Fujichrome 1600D (color slide)
- 3M 1000 (color slide)
- T-Max 3200 (black and white print)
- T-Max 400 (black and white print)

As you perfect your technique, try specialized films (i.e., specially designed and/or treated) for this type of astrophotography. Here are some popular choices:

- Ektar 125 (color print)
- Fujichrome 100D (color slide)
- Tech Pan, gas hypered (black and white print)
- T-Max 400 (black and white print)

As with all forms of photography, keep accurate records of your work. This information can be used later if you want to reproduce certain results or if you want to submit photos for possible publication.

Once you have mastered piggyback photography with wide angle and normal lenses, try longer focal length lenses. The longer the focal length, the more accurate your guiding must be. You can continue to increase the focal length of the lens until you are ready for prime focus photography with your Celestron CM-1100

Eyepiece Projection

This form of celestial photography is designed for objects with small angular sizes, primarily the Moon and planets. Planets, although physically quite large, appear small in angular size because of their great distances. Moderate to high magnification is, therefore, required to make the image large enough to see any detail. Unfortunately, the camera/telescope combination alone does not provide enough magnification to produce a usable image size on film. In order to get the image large enough, you must attach your camera to the telescope with the eyepiece in place. To do so, you need two additional accessories; a Deluxe Tele-Extender (#93643), which attaches onto the visual back, and a T-ring for your particular camera make (i.e., Minolta, Nikon, Pentax, etc.).

Because of the high magnifications during eyepiece projection, the field of view is quite small which makes it difficult to find and center objects. To make the job a little easier, align the finder as accurately as possible. This allows you to get the object in the field based on the finder view alone.

Another problem introduced by the high magnification is vibration. Simply tripping the shutter — even with a cable release — produces enough vibration to smear the image. To get around this, use the camera's self-timer if the exposure time is less than one second — a common occurrence when photographing the Moon. For exposures over one second, use the "hat trick." This technique incorporates a hand-held black card placed over the aperture of the telescope to act as a shutter. The card prevents light from entering the telescope while the shutter is released. Once the shutter has been released and the vibration has diminished (a few seconds), move the black card out of the way to expose the film. After the exposure is complete, place the card over the front of the telescope and close the shutter. Advance the film and you're ready for your next shot. Keep in mind that the card should be held a few inches in front of the telescope, and not touching it. It is easier if you use two people for this process; one to release the camera shutter and one to hold the card. Here's the process for making the exposure.

1. Find and center the desired target in the viewfinder of your camera.
2. Turn the focus knob until the image is as sharp as possible.
3. Place the black card over the front of the telescope.
4. Release the shutter using a cable release.
5. Wait for the vibration caused by releasing the shutter to diminish. Also, wait for a moment of good seeing.
6. Remove the black card from in front of the telescope for the duration of the exposure (see accompanying table).
7. Replace the black card over the front of the telescope.
8. Close the camera's shutter.

Advance the film and your ready for your next exposure. Don't forget to take photos of varying duration and keep accurate records of what you have done. Record the date, telescope, exposure duration, eyepiece, f/ratio, film, and some comments on the seeing conditions.

Download from Www.Somanuals.com. All Manuals Search And Download.

The following table lists exposures for eyepiece projection with a 10mm eyepiece. All exposure times are listed in seconds or fractions of a second.

Planet	ISO 50	ISO 100	ISO 200	ISO 400
Moon	4	2	1	1/2
Mercury	16	8	4	2
Venus	1/2	1/4	1/8	1/15
Mars	16	8	4	2
Jupiter	8	4	2	1
Saturn	16	8	4	2

Table 7-2

The exposure times listed here should be used as a starting point. Always make exposures that are longer and shorter than the recommended time. Also, try bracketing your exposures, taking a few photos at each shutter speed. This will ensure that you will get a good photo. It is not uncommon to go through an entire roll of 36 exposures and have only one shot turn out good.

Don't expect to record more detail than you can see visually in the eyepiece at the time you are photographing.

Once you have mastered the technique, experiment with different films, different focal length eyepieces, and even different filters.

Long Exposure Prime Focus

This is the last form of celestial photography to be attempted after others have been mastered. It is intended primarily for deep-sky objects, that is objects outside our solar system which includes star clusters, nebulae, and galaxies. While it may seem that high magnification is required for these objects, just the opposite is true. Most of these objects cover large angular areas and fit nicely into the prime focus field of your Celestron CM-1100 telescope. The brightness of these objects, however, requires long exposure times and, as a result, are rather difficult.

There are several techniques for this type of photography, and the one chosen will determine the standard accessories needed. If, for example, you use a separate guidescope, the camera attaches to the telescope with a T-Adapter (#93633-A) and a T-Ring for your specific camera. However, the best method for long exposure deep-sky astrophotography is with an off-axis guider. This devise allows you to photograph through the telescope and guide simultaneously. Celestron offers a very special and advanced off-axis guider, called the Radial Guider (#94176). In addition, you will need a T-Ring to attach your camera to the Radial Guider.

Other equipment needs include a guiding eyepiece. Unlike piggyback photography which allows for fairly loose guiding, prime focus requires meticulous guiding for long periods. To accomplish this you need a guiding ocular with an illuminated reticle to monitor your guide star. For this purpose, Celestron offers the Micro Guide Eyepiece (#94171). Here is a brief summary of the technique.

1. Polar align the telescope using the declination drift method.
2. Remove all visual accessories.
3. Thread the Radial Guider onto your Celestron CM-1100.
4. Thread the T-Ring onto the Radial Guider.
5. Mount your camera body onto the T-Ring the same as you would any other lens.
6. Set the shutter speed to the “B” setting.
7. Focus the telescope on a star.
8. Center your subject in the field of your camera.
9. Find a suitable guide star in the telescope field. This can be the most time consuming process.
10. Open the shutter using a cable release.
11. Monitor your guide star for the duration of the exposure.
12. Close the camera’s shutter.

Download from Www.Somanuals.com. All Manuals Search And Download.

When getting started, use fast films to record as much detail in the shortest possible time. Here are proven recommendations:

- Ektar 1000 (color print)
- Konica 3200 (color print)
- Fujichrome 1600D (color slide)
- 3M 1000 (color slide)
- T-Max 3200 (black and white print)
- T-Max 400 (black and white print)

As you perfect your technique, try specialized films (i.e., specially designed and/or treated) for this type of astrophotography. Here are some popular choices:

- Ektar 125 (color print)
- Fujichrome 100D (color slide)
- Tech Pan, gas hypered (black and white print)
- T-Max 400 (black and white print)

There is no exposure determination table to help you get started. The best way to determine exposure length is look at previously published photos to see what film/exposure combination was used. Or take unguided sample photos of various parts of the sky while the drive is running. Take exposures of various lengths to determine the best exposure time.

CCD IMAGING

Fastar Lens Assembly Option – Using your CM-1400 telescope at f/2.1 with optional PixCel CCD Camera

Only the CM-1400 is equipped with a removable secondary mirror that allows you to convert your f/11 telescope into an f/2.1 imaging system capable of exposure times 25 times shorter than those needed with a f/11 system! Used with Celestron's PixCel CCD System, objects will be easily found due to the wide .36° by .27° field of view provided. With the optional Fastar lens assembly you can easily convert your Fastar compatible telescope to f/2.1 prime focus use in a matter of seconds. Your telescope can now be used in many different f-number's for CCD imaging. It can be used at f/2.1 (with optional Fastar Lens Assembly), f/7 (with the optional Reducer/Corrector), f/11, and f/22 (with the optional 2x barlow) making it the most versatile imaging system available today. This makes the system ideal for imaging deep-sky objects as well as planetary detail. The key to the Fastar's versatility is the variety of different F-numbers in which it can be used. Described below is the significance of each F-number and the type of object best suited to that kind of imaging.

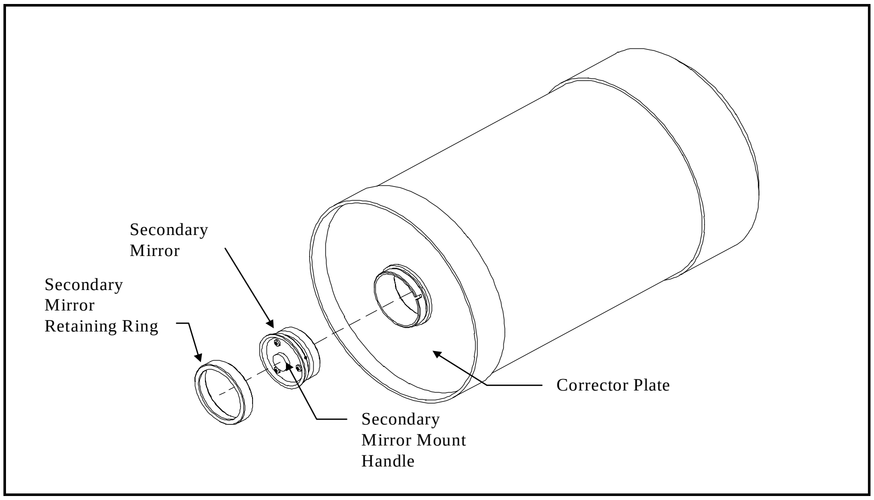

Figure 7-1

The above figure shows how the secondary mirror is removed when using the optional PixCel CCD camera at f/2.1 and the Fastar Lens Assembly (#94181).

Warning: The secondary mirror should never be removed unless installing the optional Fastar Lens Assembly. Adjustments to collimation can easily be made by turning the screws on the top of the secondary mirror mount without ever having to remove the secondary mirror (see Telescope Maintenance section of this manual).

Download from Www.Somanuals.com. All Manuals Search And Download.

Description of F-numbers

The F/# stands for the ratio between the focal length and the diameter of the light gathering element. A C14 optical tube has a focal length of 154 inches and a diameter of 14 inches. This makes the system an f/11, (focal length divided by diameter). When the secondary is removed and the CCD is placed at the Fastar position, the system becomes f/2.1, this is unique to Celestron telescopes (see figures below).

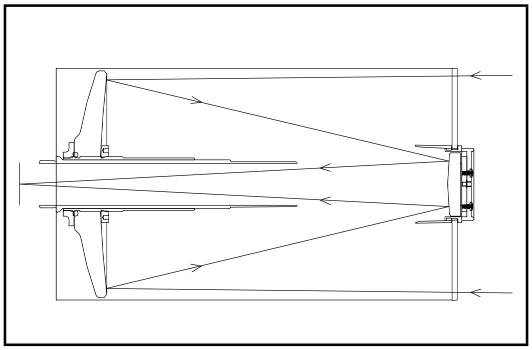

Figure 7-2 -- Light path at f/11 focus

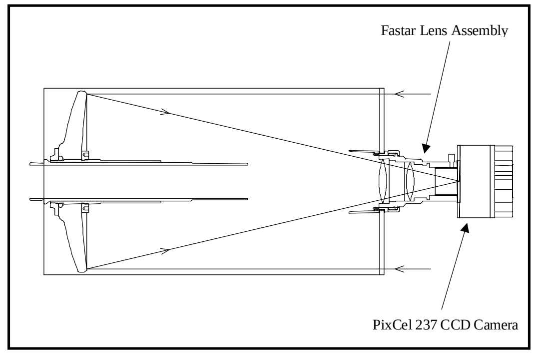

Figure 7-3 -- Light path at Fastar f/2.1 focus

The key factors for good CCD imaging are; exposure time, field-of-view, image size, and pixel resolution. As the F/# goes down (or gets faster), the exposure times needed decreases, the field-of-view-increases, but the image scale of the object gets smaller. What is the difference between f/2.1 and f/11? F/2.1 has 1/5 the focal length of f/11. That makes the exposure time needed about 25 times shorter than at f/11, the field of view 5 times larger and the object size 1/5 compared to that of f/11. (see Table below)

	Standard Cassegrain	With Reducer/Corrector Accessory	With Fastar Lens Accessory
Focal Length & Speed	154"(3910mm) @ f/11	98" (2488mm) @ f/7	29.4" (747mm) @ f/2.1
PixCel 237 F.O.V.	4.1 x 3.2 (arc min)	6.5 x 5 (arc min)	22 x 17 (arc min)

Table 7-3

Fastar Configuration

The following is a brief description of the advantages of imaging at each f-number configuration and the proper equipment needed to use the telescope in any of its many settings. Refer to Figure 7-6 for a more detailed description of the accessories offered for each configuration.

Download from Www.Somanuals.com. All Manuals Search And Download.

Imaging at f/2.1

As stated above, the exposure times are much shorter at f/2.1 than at f/7 or f/11. The field-of-view is wider, so it is easier to find and center objects. Also with a wider field-of-view you can fit larger objects (such as M51, The Whirlpool Galaxy) in the frame. Typical exposure times can be 20-30 seconds for many objects. With the Track and Accumulate function on the PixCel software (see the PixCel Operating Manual for more details about its software features), the camera can shoot and stack several images automatically without ever having to guide the exposure. Under dark skies you can get an excellent image of the Dumbbell Nebula (M27) with only a few 30 second exposures (see figure 7-4 below). The spiral arms of the Whirlpool galaxy (Figure 7-5) can be captured with a 30 second exposure and can be improved upon dramatically if several 30-60 second exposures are added together using the Track and Accumulate™ feature.

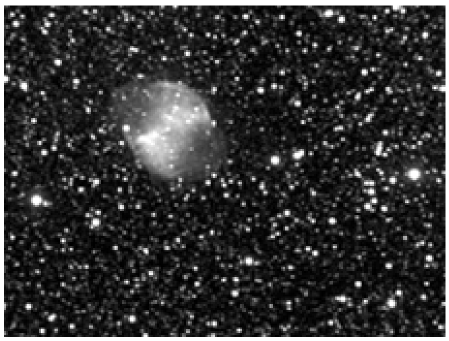

Figure 7-4 M27 -- The Dumbbell Nebula
4 exposures of 30 seconds each!

Figure 7-5 M51 -- The Whirlpool Nebula
9 exposures of 60 seconds each.

When imaging some objects like planetary nebula (for example M57, the Ring Nebula) and small galaxies (M104, the Sombrero Galaxy), larger image scale is needed to resolve finer detail. These objects are better shot at f/7 or even f/11.

Imaging at f/7

Medium size to small galaxies --
f/7 imaging gives you finer resolution then at f/2.1, but the slower f-number will usually require you to guide the image while you are taking longer exposures. Guiding can be accomplished by using an optional Radial Guider or a piggyback guidescope. The exposure times are about 10 times longer but the results can be worth the extra effort. There are some objects that are small enough and bright enough that they work great at f/7. M104 (the Sombrero Galaxy) can be imaged under dark skies with a series of short exposures using Track and Accumulate. Ten exposures at 15 seconds each will yield a nice image and is short enough that you may not need to guide the exposure at all. For f/7 imaging the optional Reducer/Corrector is needed. (See Optional Accessory section at the end of this manual).

Imaging at f/11

Lunar or small planetary nebulae--
f/11 imaging is more challenging for long exposure, deep-sky imaging. Guiding needs to be very accurate and the exposure times need to be much longer, about 25 times longer than f/2.1. There are only a select few objects that work well at f/11. The moon images fine because it is so bright, but planets are still a bit small and should be shot at f/22. The Ring nebula is a good candidate because it is small and bright. The Ring Nebula (M57) can be imaged in about 30-50 seconds at f/11. The longer the exposure the better.

Download from Www.Somanuals.com. All Manuals Search And Download.

Imaging at f/22

Planetary or Lunar--

f/20 is a great way to image the planets and features on the moon. With the PixCel CCD camera and optional Color Filter Wheel, it is easy to take tri-color images of planets also. When imaging the planets, very short exposures are needed. Many cameras have trouble taking images under .1 seconds. The PixCel camera can image at .01 seconds exposures due to the design of the CCD array. The exposure lengths range from .03 to .1 seconds on planetary images. Focus is critical as is good atmospheric conditions. Generally you will take one image after another until one looks good (see AutoGrab feature in the PixCel Operating Manual). This is due to the atmospheric “seeing” conditions. For every 10 exposures you might save 1. To image at f/22 you need to purchase a 2x Barlow and a T-adapter or Radial Guider.

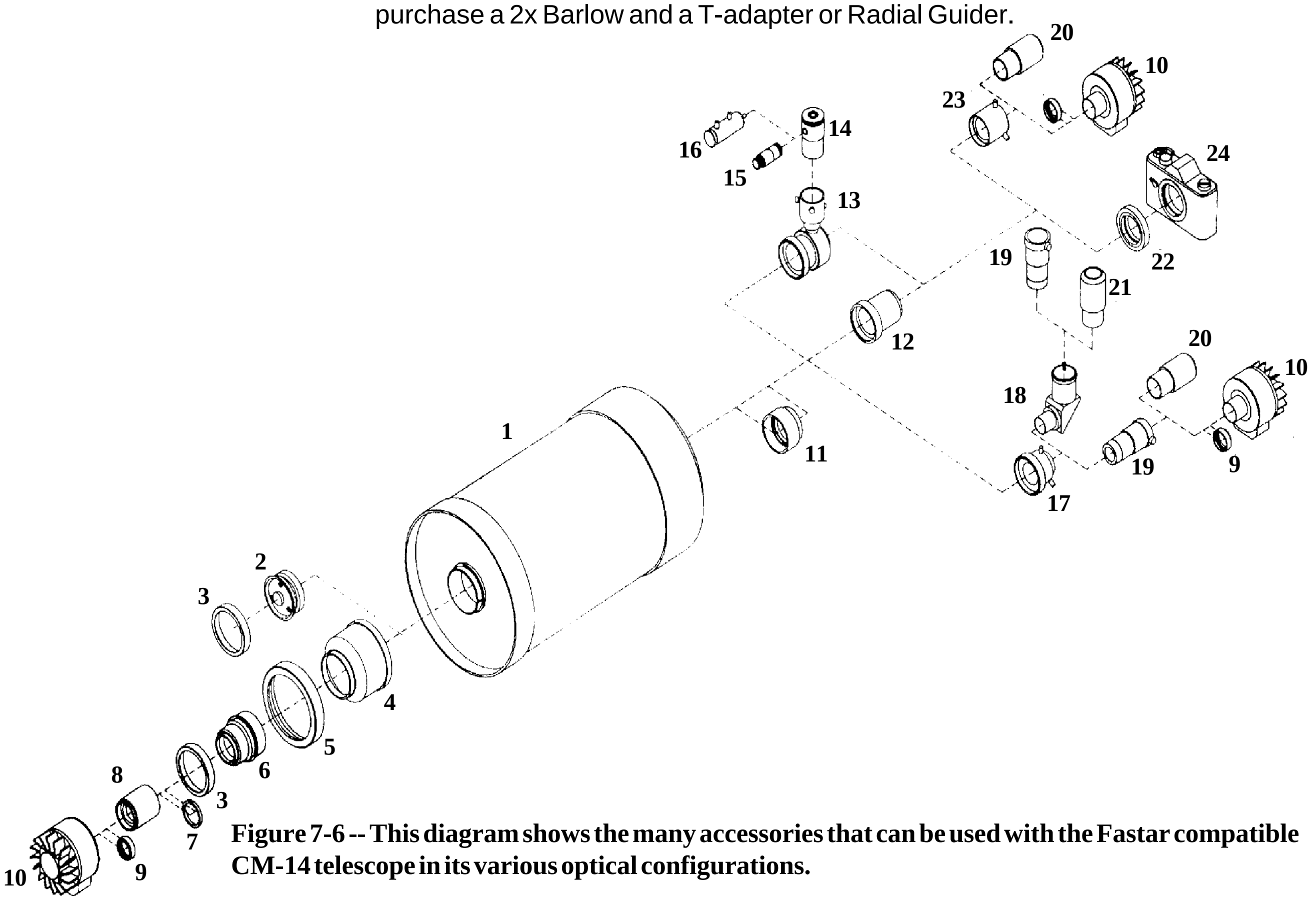

Figure 7-6 -- This diagram shows the many accessories that can be used with the Fastar compatible CM-14 telescope in its various optical configurations.

1	Optical Tube Assembly	13	Radial Guider
2	Secondary Mirror	14	Microguide Eyepiece
3	Secondary Mirror Retaining Ring	15	Illuminator (Microguide Eyepiece only)
4	Fastar Lens Spacer	16	Pulstar Illuminator
5	Fastar Spacer Retaining Ring	17	Visual Back 1 ¼”
6	Fastar Lens Assembly	18	Star Diagonal
7	Tricolor Spacer Ring	19	2X Barlow Lens
8	Fastar 14 T-Adapter	20	Cross Hair Eyepiece
9	IR Cutoff Filter	21	26mm Plossl Eyepiece
10	PixCel CCD Camera	22	T-Ring
11	Reducer/Corrector f/6.3	23	T - 1 $^{1}/_{4}$" Adapter
12	T-Adapter	24	35mm SLR Camera

TELESCOPE MAINTENANCE

While your CM-1100 telescope requires little maintenance, there are a few things to remember that will ensure your telescope performs at its best.

Care and Cleaning of the Optics

Occasionally, dust and/or moisture may build up on the corrector plate of your telescope. Special care should be taken when cleaning any instrument so as not to damage the optics.

If dust has built up on the corrector plate, remove it with a brush (made of camel's hair) or a can of pressurized air. Spray at an angle to the lens for approximately two to four seconds. Then, use an optical cleaning solution and white tissue paper to remove any remaining debris. Apply the solution to the tissue and then apply the tissue paper to the lens. Low pressure strokes should go from the center of the corrector to the outer portion. **Do NOT rub in circles!**

You can use a commercially made lens cleaner or mix your own. A good cleaning solution is isopropyl alcohol mixed with distilled water. The solution should be 60% isopropyl alcohol and 40% distilled water. Or, liquid dish soap diluted with water (a couple of drops per one quart of water) can be used.

Occasionally, you may experience dew build-up on the corrector plate of your telescope during an observing session. If you want to continue observing, the dew must be removed, either with a hair dryer or by pointing the telescope at the ground until the dew has evaporated.

If moisture condenses on the inside of the corrector, remove the accessories from the rear cell of the telescope. Place the telescope in a dust-free environment and point it down. This will remove the moisture from the telescope tube.

To minimize the need to clean your telescope, replace all lens covers once you have finished using it. Since the rear cell is NOT sealed, the cover should be placed over the opening when not in use. This will prevent contaminants from entering the optical tube.

Internal adjustments and cleaning should be done only by the Celestron repair department. If your telescope is in need of internal cleaning, please call the factory for a return authorization number and price quote.

Collimation

The optical performance of your Celestron CM-1100 telescope is directly related to its collimation, that is the alignment of its optical system. Your Celestron CM-1100 was collimated at the factory after it was completely assembled. However, if the telescope is dropped or jarred severely during transport, it may have to be collimated. The only optical element that may need to be adjusted, or is possible, is the tilt of the secondary mirror.
To check the collimation of your telescope you will need a light source. A bright star near the zenith is ideal since there is a minimal amount of atmo-

Download from Www.Somanuals.com. All Manuals Search And Download.

spheric distortion. Turn your telescope drive on so that you won't have to manually track the star. Or, if your are not using the clock drive, use Polaris. Its position relative to the celestial pole means that it moves very little thus eliminating the need to manually track it.

Before you begin the collimation process, be sure that your telescope is in thermal equilibrium with the surroundings. Allow 45 minutes for the telescope to reach equilibrium if you move it between large temperature extremes.

To verify collimation, view a star near the zenith. Use a medium to high power ocular — 12mm to 6mm focal length. It is important to center a star in the center of the field to judge collimation.   Slowly cross in and out of focus and judge the symmetry of the star. If you see a systematic skewing of the star to one side, then recollimation is needed.

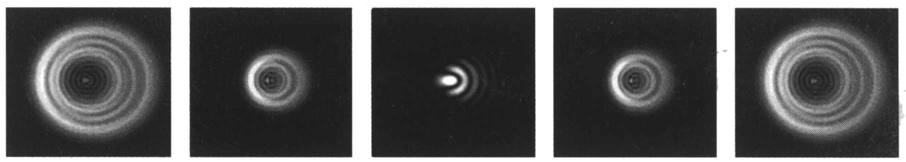

Figure 8-1 -- Even though the star pattern appears the same on both sides of focus, they are asymmetric. The dark obstruction is skewed off to the left side of the diffraction pattern indicating poor collimation.

To accomplish this, you need to tighten the secondary collimation screw(s) that move the star across the field toward the direction of the skewed light. These screws are located in the secondary mirror holder. Make only a small 1/6 to 1/8 field correction and recenter the star by moving the scope before making any improvements or before making further adjustments.

To make collimation a simple procedure, follow these easy steps:

1. While looking through a medium to high power eyepiece, de-focus a bright star until a ring pattern with a dark shadow appears (see figure 8-1). Center the de-focused star and notice in which direction the central shadow is skewed.

2. Place your finger (or the finger of a friend) along the edge of the front cell of the telescope, pointing towards the collimation screws. the shadow of your finger should be visible when looking into the eyepiece. Rotate your finger around the tube edge until its shadow is seen closest to the narrowest portion of the rings (ie. the same direction in which the central shadow is skewed).

3. Locate the collimation screw closest to where your finger is positioned. This will be the collimation screw you will need to adjust first. (If your finger is positioned exactly between two of the collimation screws, then you will need to adjust the screw opposite where your finger is located).

4. Use the slow motion controls to move the de-focused star image to the edge of the field of view, in the same direction that the central obstruction of the star image is skewed.

Download from Www.Somanuals.com. All Manuals Search And Download.

5 While looking through the eyepiece, use a screwdriver to turn the collimation screw you located in step 2 and 3. Usually a tenth of a turn is enough to notice a change in collimation. If the star image moves out of the field of view in the direction that the central shadow is skewed, than you are turning the collimation screw the wrong way. Turn the screw in the opposite direction, so that the star image is moving towards the center of the field of view.

If while turning you notice that the screws get very loose, than simply tighten the other two screws by the same amount. Conversely, if the collimation screw gets too tight, then loosen the other two screws by the same amount.

6 Once the star image is in the center of the field of view, check to see if the rings are concentric. If the central obstruction is still skewed in the same direction, then continue turning the screw(s) in the same direction. If you find that the ring pattern is skewed in a different direction, than simply repeat steps 2 through 6 as described above for the new direction.

Perfect collimation will yield a star or planetary image very symmetrical just inside and outside of focus. In addition, perfect collimation delivers the optimal optical performance specifications that your telescope is built to achieve.

If seeing (i.e., air steadiness) is turbulent, collimation is difficult to judge. Wait until a better night if it is turbulent or aim to a steadier part of the sky. A steadier part of the sky is judged by steady versus twinkling stars.

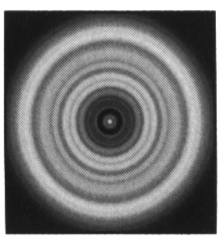

Figure 8-2
A collimated telescope should appear symmetrical with the central obstruction centered in the star's diffraction pattern.

OPTIONAL ACCESSORIES

The following is a partial list of optional accessories available for your Celestron CM-1100/1400. You will find that additional accessories enhance your viewing pleasure and expand the usefulness of your telescope. For ease of reference, all the accessories are listed in alphabetical order.

AC Adapter - 110V - 60Hz (#18770) - The AC Adapter allows you to run your CM telescope off of AC rather than the standard DC battery.

Advanced Astro Master (#93900) - This unique accessory contains a data base of more than 10,000 objects! Included are the Messier catalog, NGC catalog, IC catalog, portions of the ESO catalog, portions of the UGC catalog, special non-stellar catalog which contains objects not found in any of the other catalogs, a star catalog containing 241 interesting double and multiple stars, and a user definable catalog that allows you to enter 25 of your favorite objects. And, scrolling information cross references Sky Atlas 2000.0 or Uranometria . Unlike other digital setting circles, which require the use of a clock drive, the Advanced Astro Master can be used with or without a clock drive. All you have to do is align on any two of the 28 navigational alignment stars in the Advanced Astro Master's data base and you are ready to observe. Once aligned, the system keeps track of where it is pointed. And, the Advanced Astro Master has an RS-232 port for complete interface to your personal computer. The RS-232 cable **(#93921)** is available. The encoder installation kit for the CI-700 mount is **#93908.**

Barlow Lenses - A Barlow lens is a negative lens that increases the focal length of a telescope. Used with any eyepiece, it doubles the magnification of that eyepiece. Celestron offers two Barlow lenses in the 1-1/4" size. The 2x Ultima Barlow (#93506) is a compact triplet design that is fully multicoated for maximum light transmission and parfocal when used with the Ultima eye-pieces. It works very well with all Celestron eyepieces. The latest Barlow to be added to Celestron's product line (#93507) is a low profile achromatic design. It weighs just 4 oz. and it is under 3" in length.

Counterweight - 11 lbs. - Extra counterweights **(#94195)** may be necessary when using heavy accessories.

2" Mirror Diagonal (#93519) -For the CM-1100 (Standard on CM-1400). Like the l-$^{l}/_{4}$" Prism Star Diagonals, the 2" Mirror Diagonal allows you to use 2" eyepieces with your Celestron telescope. These larger eyepieces offer wider fields and better eye relief for greater viewing comfort. **This accessory is <u>NOT</u> recommended for use with the Reducer/Corrector Lens.**

Erect Image Diagonal (#94112-A) - For daytime terrestrial viewing the Erect Image Diagonal produces images through your Schmidt-Cassegrain telescope that match what you see with the unaided eye. This accessory uses an Amici

Download from Www.Somanuals.com. All Manuals Search And Download.

prism arrangement that, in addition to producing correctly oriented images, allows you to look into the telescope at a 45° angle, a desirable arrangement for terrestrial viewing.

Eyepiece Filters - To enhance your visual observations of planetary objects, Celestron offers a wide range of colored filters that thread into the 1-1/4" oculars. Available are: #12 Deep Yellow, #21 Orange, #25 Red, #58 Green, #80A Light Blue, #96 Neutral Density (25% T, and 13% T) and Polarizing filters. These and other filters are also sold in sets.

Eyepieces - Like telescopes, eyepieces come in a variety of designs. And, with the advent of different eyepieces, Celestron also has a variety of designs each with its own advantages and disadvantages. For the 1-1 /4" barrel diameter there are four different eyepiece designs available.

•**SMA** - The SMA design is an improved version of the Kellner eyepiece. SMA's are very good, economical, general purpose eyepieces. Available in focal lengths of 6mm, 10mm, 12mm, and 25mm.

•**Plossl** - Plossl eyepieces have a 4-element lens designed for low-to-high power observing. The Plossls offer razor sharp views across the entire field, even at the edges! In the 1-1 /4" barrel diameter, they are available in the following focal lengths: 6.3mm, 7.5mm, 10mm, 12.5mm, 17mm, 20mm, 26mm, 32mm, and 40mm.

•**Ultima** - Ultima is not really a design, but a trade name for our 5-element, wide field eyepieces. In the 1-1/4" barrel diameter, they are available in the following focal lengths: 5mm, 7.5mm, 12.5mm, 18mm, 24mm, 30mm, 35mm, and 42mm. These eyepieces are all parfocal. The 35mm Ultima gives the widest possible field of view with a 1-1 /4" diagonal and is ideal for use with the Reducer/Corrector.

•**Lanthanum Eyepieces (LV Series)** - Lanthanum is a unique rare earth glass used in one of the field lenses of this new eyepiece. The Lanthanum glass reduces aberrations to a minimum. All are fully multicoated and have an astounding 20mm of eye relief—perfect for eyeglass wearers! In the 1-1/4" barrel diameter, they are available in the following focal lengths: 2.5mm, 4mm, 5mm, 6mm, 9mm, 10mm, 12mm, 15mm, 20mm and 25mm. Also available is an LV Zoom Eyepiece with the focal length range of 8 to 24 mm.

In addition to the previously mentioned, there is also a deluxe compact zoom ocular (#93306) that has a variable focal length of 6.5 to 18mm.

Finderscopes - Finderscopes are used to help you locate objects in the main telescope. The larger the finderscope, the more you will see, making it easier to locate objects. One option for finders is the illuminated Polaris 7x50 Finder **(#93785-8P).** It comes with the bracket, finderscope, and illuminator. There is also a Quick Release Finder bracket **(#51149-A)** which allows you to easily remove and replace the finderscope without losing alignment. The Quick Release Bracket is only available for the 9x50 and 7x50 Finderscopes.

Another tool for finding objects in the sky is the **Star Pointer (#51630)**. The Star Pointer is different from a finderscope in that you can use both eyes when pointing the telescope at an object. A partially reflective surface projects the image of an LED illuminated pinpoint into the line of sight. Just align the illuminated pinpoint with the object you are interested in and the object will be

Download from Www.Somanuals.com. All Manuals Search And Download.

in the main telescope.

Flashlight (#93592) - The LED flashlight uses a red LED to allow reading star maps without ruining your night vision. The LED flashlight is small, only 6 inches long, and weighs in at a mere 3 ounces.

Flashlight, Night Vision (#93588) - Celestron's premium model for astronomy, using two red LEDs to preserve night vision. The brightness is adjustable and it operates on a single 9 Volt battery.

Light Pollution Reduction (LPR) Filters - These filters are designed to enhance your views of deep-sky astronomical objects when viewed from urban areas. LPR Filters selectively reduce the transmission of certain wavelengths of light, specifically those produced by artificial lights. This includes mercury and high and low pressure sodium vapor lights. In addition, they also block unwanted natural light (sky glow) caused by neutral oxygen emission in our atmosphere. Celestron offers a model for 1-l/4" eyepieces **(#94126A)** and a model that attaches to the rear cell ahead of the star diagonal and visual back **(#94127A)**.

Micro Guide Eyepiece (#94171) - This multipurpose illuminated 12.5mm reticle can be used for guiding deep-sky astrophotos, measuring position angles, angular separations, and more. The laser etched reticle provides razor sharp lines and the variable brightness illuminator is completely cordless.

Piggyback Mount (#93598) - The best way to enter the realm of deep-sky photography is via the piggyback method. Piggyback photography allows you to record constellations and large scale nebulae that don't fit in the field of your telescope. The piggyback mount allows you to attach a camera to the top of the telescope. This way, the camera can photograph with its normal or wide angle lens while you guide through the telescope. The piggyback mount attaches to the rear cell of the telescope next to the finder.

Polarizing Filter Set (#93608) - The polarizing filter set limits the transmission of light to a specific plane, thus increasing contrast between various objects. This is used primarily for terrestrial, lunar, and planetary observing.

Radial Guider (#94176) - The Celestron Radial Guider is specifically designed for use in prime focus, deep-sky astrophotography and takes the place of the T-Adapter. This device allows you to photograph and guide simultaneously through the optical tube assembly of your telescope. This type of guiding produces the best results since what you see through the guiding eyepiece is exactly reproduced on the processed film. The Radial guider is a "T"-shaped assembly that attaches to the rear cell of the telescope. As light from the telescope enters the guider, most passes straight through to the camera. A small portion, however, is diverted by a prism at an adjustable angle up to the guiding eyepiece. This guider has two features not found on other off-axis guiders; first, the prism and eyepiece housing rotate independently of the camera orientation making the acquisition of a guide star quite easy. Second, the prism angle is tunable allowing you to look at guide stars on-axis. This accessory works especially well with the Reducer/Corrector.

Reducer/Corrector (#94175) - This lens reduces the focal length of the telescope by 37%, making your CM-1100 a l,764mm f/6.3 instrument. In addition, this unique lens also corrects inherent aberrations to produce crisp images all the way across the field. It also increases the field of view significantly and is ideal for wide-field, deep-sky viewing. It is perfect for beginning

Download from Www.Somanuals.com. All Manuals Search And Download.

prime focus long-exposure astrophotography. It makes guiding easier and exposures shorter.

Sky Maps (#93722) - When learning the night sky, the Celestron Sky Maps offer the ideal solution. The maps include all the constellations and brighter deep-sky objects. The maps are printed on a heavy stock paper that is moisture-resistant. On the front cover is a rotating planisphere which indicates when specific constellations are visible.

Skylight Filter (#93621) - The Skylight Filter is used on Celestron Schmidt-Cassegrain telescopes as a dust seal. The filter threads onto the rear cell of your telescope. All other accessories, both visual and photographic, thread onto the Skylight Filter. Although it does cut down on a portion of the incoming light, it is a very small amount. It should be noted, that most Barlow lenses can NOT be inserted into the visual back when the skylight filter is attached.

T-Adapter (#93633-A) - A T-Adapter (with T-Ring) allows you to attach your camera to the prime focus of a Celestron Schmidt-Cassegrain telescope. This is used for terrestrial photography and short exposure lunar and filtered solar photography. It can be used for long exposure deep-sky photography if you use a separate guidescope.

T-C Adapter (#93636) - This adapter allows you to couple a video or movie camera to a telescope. The camera must have a removable lens with a standard "C" thread. The T-C adapter threads into the camera and then onto the T-Adapter.

T-Ring - The T-Ring couples your camera body to the T-Adapter, Radial Guider Body, or Tele-Extender. This accessory is mandatory if you want to do astrophotography through the telescope. Each camera make (i.e., Minolta, Nikon, etc.) has its own unique mount and therefore, its own T-Ring.

Tele-Extender, Deluxe (#93643) - The tele-extender is a hollow tube that allows you to attach a camera to the telescope when the eyepiece is installed. This accessory is used for eyepiece projection photography which allows you to capture very high power views of the Sun, Moon, and planets on film. The tele-extender fits over the eyepiece onto the visual back and works with eyepieces that have large housings, like the Celestron Ultima series.

A full description of all Celestron accessories can be found in the Celestron Accessory Catalog (#93685).

THE MESSIER CATALOG

The Messier Catalog, compiled by Charles Messier, was the first extensive listing of star clusters and nebulae. Messier's primary observational purpose was to discover comets. He compiled this list so that others searching for comets would not be confused by these objects. His list still remains popular today because all of these objects are easily visible in amateur telescopes.

FOR FURTHER READING

The following is a list of astronomy books that will further enhance your understanding of the night sky. The books are broken down by classification for easy reference.

Astronomy Texts

Astronomy Now	Pasachoff & Kutner
Cambridge Atlas Of Astronomy	Audouze & Israel
McGraw-Hill Encyclopedia Of Astronomy	Parker
Astronomy-The Evolving Universe	Zeilik

Atlases

Atlas Of Deep Sky Splendors	Vehrenberg
Sky Atlas 2000.0	Tirion
Sky Catalog 2000.0 Vol 1 & 2	Hirshfeld & Sinnott
Uranometria Vol. 1 & 2	Tirion, Rappaport, Lovi
Magnitude 6 Star Atlas	Dickinson, Costanzo, Chaple
NGC 2000.0	Sinnott

General Observational Astronomy

The Cambridge Astronomy Guide	Liller & Mayer
A Complete Manual Of Amateur Astronomy	Sherrod
The Guide To Amateur Astronomy	Newton & Teece

Visual Observation

Observational Astronomy For Amateurs	Sidgwick
Astronomical Calendar	Ottewell
Burnham's Celestial Handbook Vols. 1, 2 & 3	Burnham
The Planet Jupiter	Peek
Field Guide To The Stars & Planets	Menzel & Pasachoff
Observe Comets	Edberg & Levy

Astrophotography

Skyshooting	Mayall & Mayall
Astrophotography A Step-by-Step Approach	Little
Astrophotography For The Amateur	Covington
Astrophotography	Gordon
Astrophotography II	Martinez
A Manual Of Celestial Photography	King
Manual Of Advanced Celestial Photography	Wallis & Provin
Colours Of The Stars	Malin & Muirden

CELESTRON ONE YEAR WARRANTY

A. Celestron International (CI) warrants this telescope to be free from defects in materials and workmanship for one year. CI will repair or replace such product or part thereof which, upon inspection by CI, is found to be defective in materials or workmanship. As a condition to the obligation of CI to repair or replace such product, the product must be returned to CI together with proof-of-purchase satisfactory to CI.

B. The Proper Return Authorization Number must be obtained from CI in advance of return. Call Celestron at (310) 328-9560 to receive the number to be displayed on the outside of your shipping container.

All returns must be accompanied by a written statement setting forth the name, address, and daytime telephone number of the owner, together with a brief description of any claimed defects. Parts or product for which replacement is made shall become the property of CI.

The customer shall be responsible for all costs of transportation and insurance, both to and from the factory of CI, and shall be required to prepay such costs.

CI shall use reasonable efforts to repair or replace any telescope covered by this warranty within thirty days of receipt. In the event repair or replacement shall require more than thirty days, CI shall notify the customer accordingly. CI reserves the right to replace any product which has been discontinued from its product line with a new product of comparable value and function.

This warranty shall be void and of no force of effect in the event a covered product has been modified in design or function, or subjected to abuse, misuse, mishandling or unauthorized repair. Further, product malfunction or deterioration due to normal wear is not covered by this warranty.

CI DISCLAIMS ANY WARRANTIES, EXPRESS OR IMPLIED, WHETHER OF MERCHANTABILITY OF FITNESS FOR A PARTICULAR USE, EXCEPT AS EXPRESSLY SET FORTH HEREIN.

THE SOLE OBLIGATION OF CI UNDER THIS LIMITED WARRANTY SHALL BE TO REPAIR OR REPLACE THE COVERED PRODUCT, IN ACCORDANCE WITH THE TERMS SET FORTH HEREIN. CI EXPRESSLY DISCLAIMS ANY LOST PROFITS, GENERAL, SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES WHICH MAY RESULT FROM BREACH OF ANY WARRANTY, OR ARISING OUT OF THE USE OR INABILITY TO USE ANY CI PRODUCT. ANY WARRANTIES WHICH ARE IMPLIED AND WHICH CANNOT BE DISCLAIMED SHALL BE LIMITED IN DURATION TO A TERM OF ONE YEAR FROM THE DATE OF ORIGINAL RETAIL PURCHASE.

Some states do not allow the exclusion or limitation of incidental or consequential damages or limitation on how long an implied warranty lasts, so the above limitations and exclusions may not apply to you.

This warranty gives you specific legal rights, and you may also have other rights which vary from state to state.

CI reserves the right to modify or discontinue, without prior notice to you, any model or style telescope.

If warranty problems arise, or if you need assistance in using your telescope contact:

Celestron International
Customer Service Department
2835 Columbia Street
Torrance, CA 90503
Tel. (310) 328-9560
Fax. (310) 212-5835
Monday-Friday 8AM-4PM PST

This warranty supersedes all other product warranties.

0698

NOTE: This warranty is valid to U.S.A. and Canadian customers who have purchased this product from an Authorized CI Dealer in the U.S.A. or Canada. Warranty outside the U.S.A. and Canada is valid only to customers who purchased from a CI International Distributor or Authorized CI Dealer in the specific country and please contact them for any warranty service.
